SwissFEL Workshop 2: Scattering and diffraction experiments

Contribution ID: 21

Type: not specified

Femtosecond analysis of protein nanocrystals and supramolecular complexes.

Monday, 21 November 2011 10:50 (5 minutes)

Membrane proteins (MPs) represent key components of cell membranes, about one fourth of the human proteome and 60% of the drug targets. We are interested in learning about the different conformations a MP can adopt in response to interacting molecules. The best way to analyse this at the atomic level is to determine their 3D-structure by crystal X-ray diffraction. We aim at producing nanocrystals of MPs and of supramolecular complexes, especially those related to tubulin, for analysis with FELs. A range of techniques will have to be employed for nanocrystal detection. Nanocrystals may exhibit fewer lattice imperfections compared to larger crystals. The x-ray beam parameters needed to analyse nanocrystals by "diffract-and-destroy"serial crystallography will be discussed as well as the way to deliver the nanocrystals to the beam.

Primary author: Dr PANNEELS, valerie (Paul Scherrer Institute)

Co-authors: Dr TSAI, Ching-Ju (Paul Scherrer Institute); Prof. SCHERTLER, Gebhard (Paul Scherrer Institute); Dr CAPITANI, Guido (Paul Scherrer Institute); Dr LI, Xiao-Dan (Paul Scherrer Institute)

Presenter: Dr PANNEELS, valerie (Paul Scherrer Institute)

Session Classification: Poster Presentation
