## Mapping of the magnetic field in the n2EDM experiment

*Tuesday, 18 October 2022 16:45 (1 minute)*

The uniformity of the magnetic field inside the inner part of the n2EDM experiment is a crucial condition to achieve the desired sensitivity of  $10^{-28} e\text{ cm}$  for the neutron electric dipole moment (EDM). The magnetic-field mapper is a dedicated nonmagnetic robot designed to measure the magnetic field at any point of a large cylindrical volume ( $0 \leq \rho \leq 780\text{ mm}$ ,  $0 \leq \phi \leq 360^\circ$ ,  $-410 \leq z \leq 410\text{ mm}$ ). It was installed in the n2EDM setup in 2021 and has been playing a key role in the n2EDM experiment preparation. Its purpose during the first mapping campaign is to characterize and qualify the inner parts of n2EDM: the remanent field inside the MSR, the production of the  $1\mu\text{T}$  neutron holding field, the magnetic purity of the octagonal vacuum tank.
