Low-energy effective field theory below the electroweak scale: one-loop renormalization in the 't Hooft-Veltman scheme

Tuesday, 18 October 2022 16:13 (1 minute)

We perform the one-loop renormalization of the low-energy effective field theory (LEFT) in the 't Hooft-Veltman (HV) scheme for γ_5 . We extend the LEFT operator basis by the required set of evanescent operators. Instead of using a pure $\overline{\rm MS}$ procedure, we renormalize physical operators such that they absorb the finite effects from insertions of evanescent operators as well as finite chiral-symmetry-breaking terms. Our results can be applied to one-loop LEFT calculations in the HV scheme: using our renormalization scheme instead of pure $\overline{\rm MS}$ leads to results that are manifestly free of spurious chiral-symmetry-breaking terms.
