SCOPE OF WORK

For the design of FCC trajectory, a full understanding of the subsurface geology that will be crossed by both the tunnel and the access shafts is required.

Objective: A detailed knowledge of the regional rock composition and structural elements such as fault of the subsurface and the hydrogeological characteristics of the area across the FCC trajectory.

This project has two goals:

I) establish a Geographic Information System (GIS)-based subsurface data set and data base architecture in support of the feasibility and execution of the FCC tunneling work

II) establish a consistent high-resolution 3D geological model, supported by quantitative geological analytical investigations along the FCC trace aimed at predicting geological features and possible risks in support of tunneling design, planning and execution.

SUBSURFACE DATA BASE

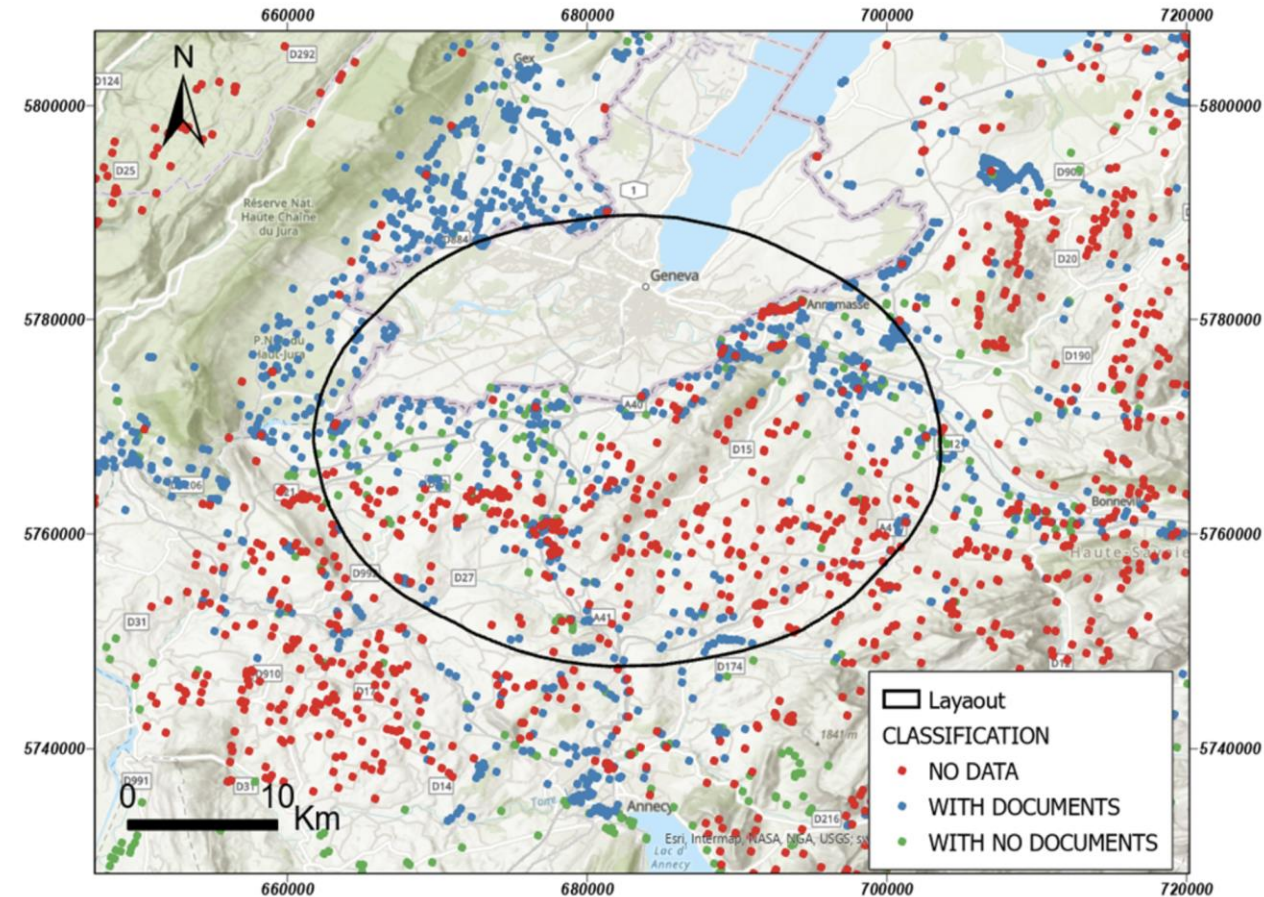

Boreholes data and classification

Source: SiTG (Canton of Geneva)

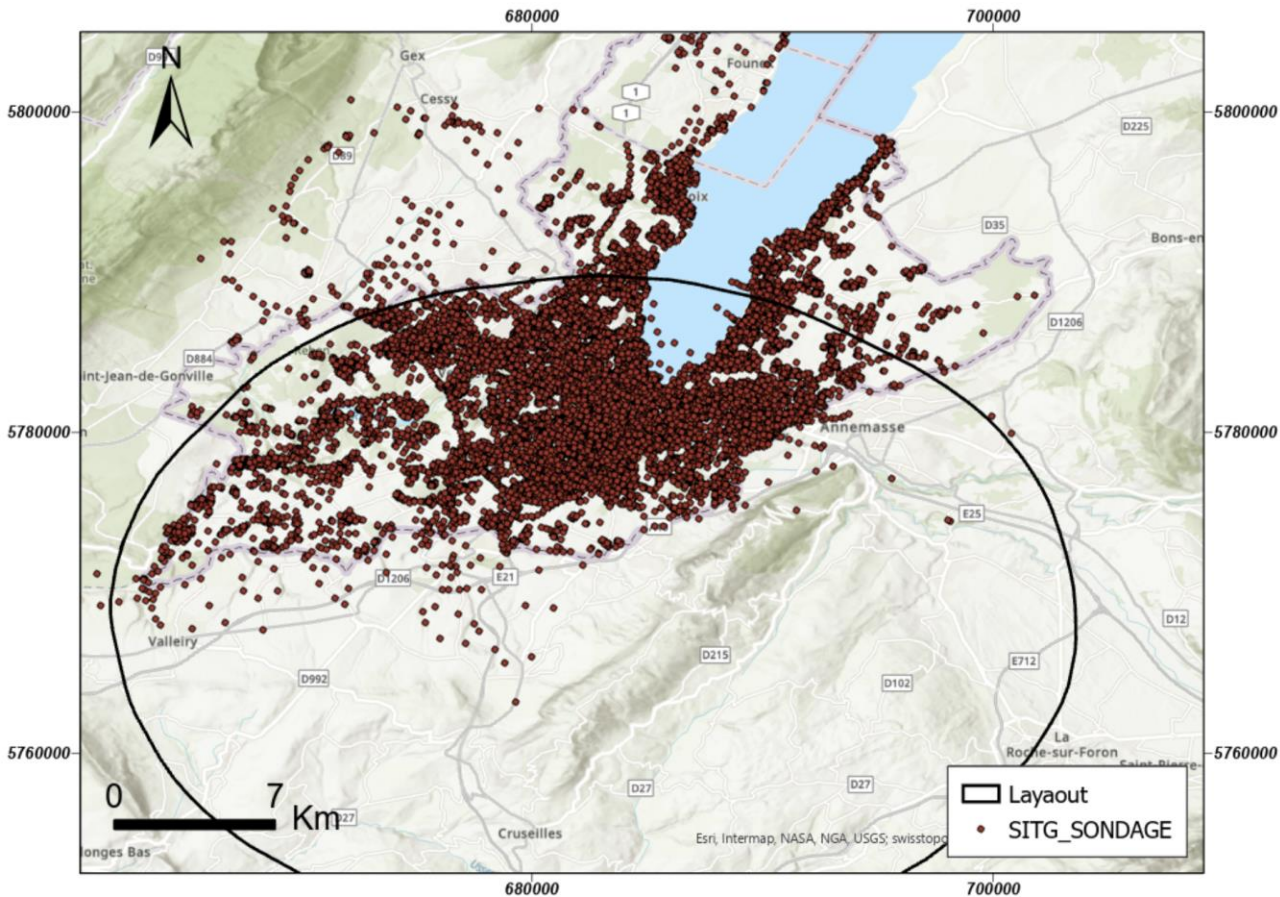

18'000 boreholes , 8969 public wells and 347 are >50m deep

Source: BRGM

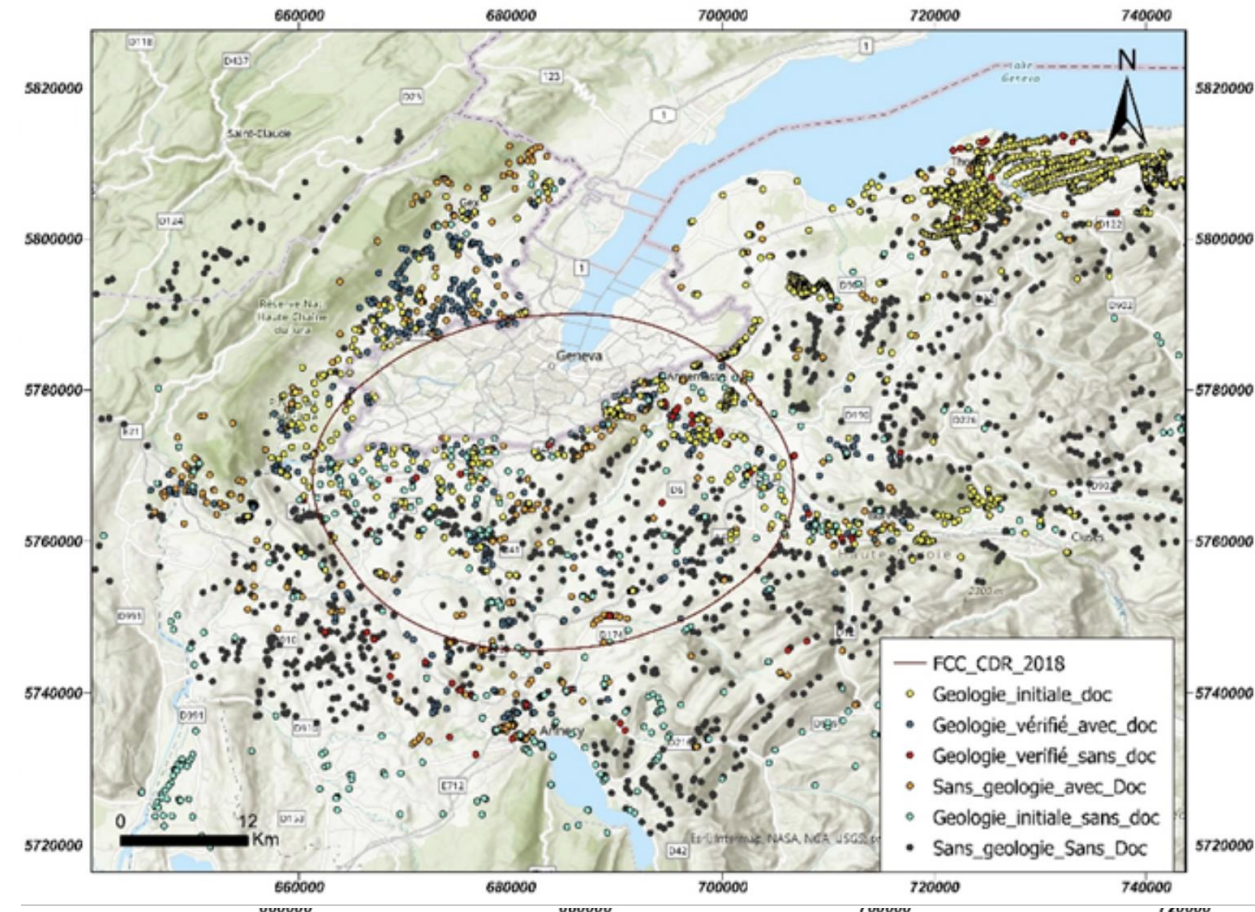

5078 boreholes , 1659 with documents

3D Geomodel dataset

- Deep boreholes with associated wireline data
- 2500 km of 2D seismic lines are available in the area – a large majority were not acquired and are not reprocessed for shallow depth interpretations

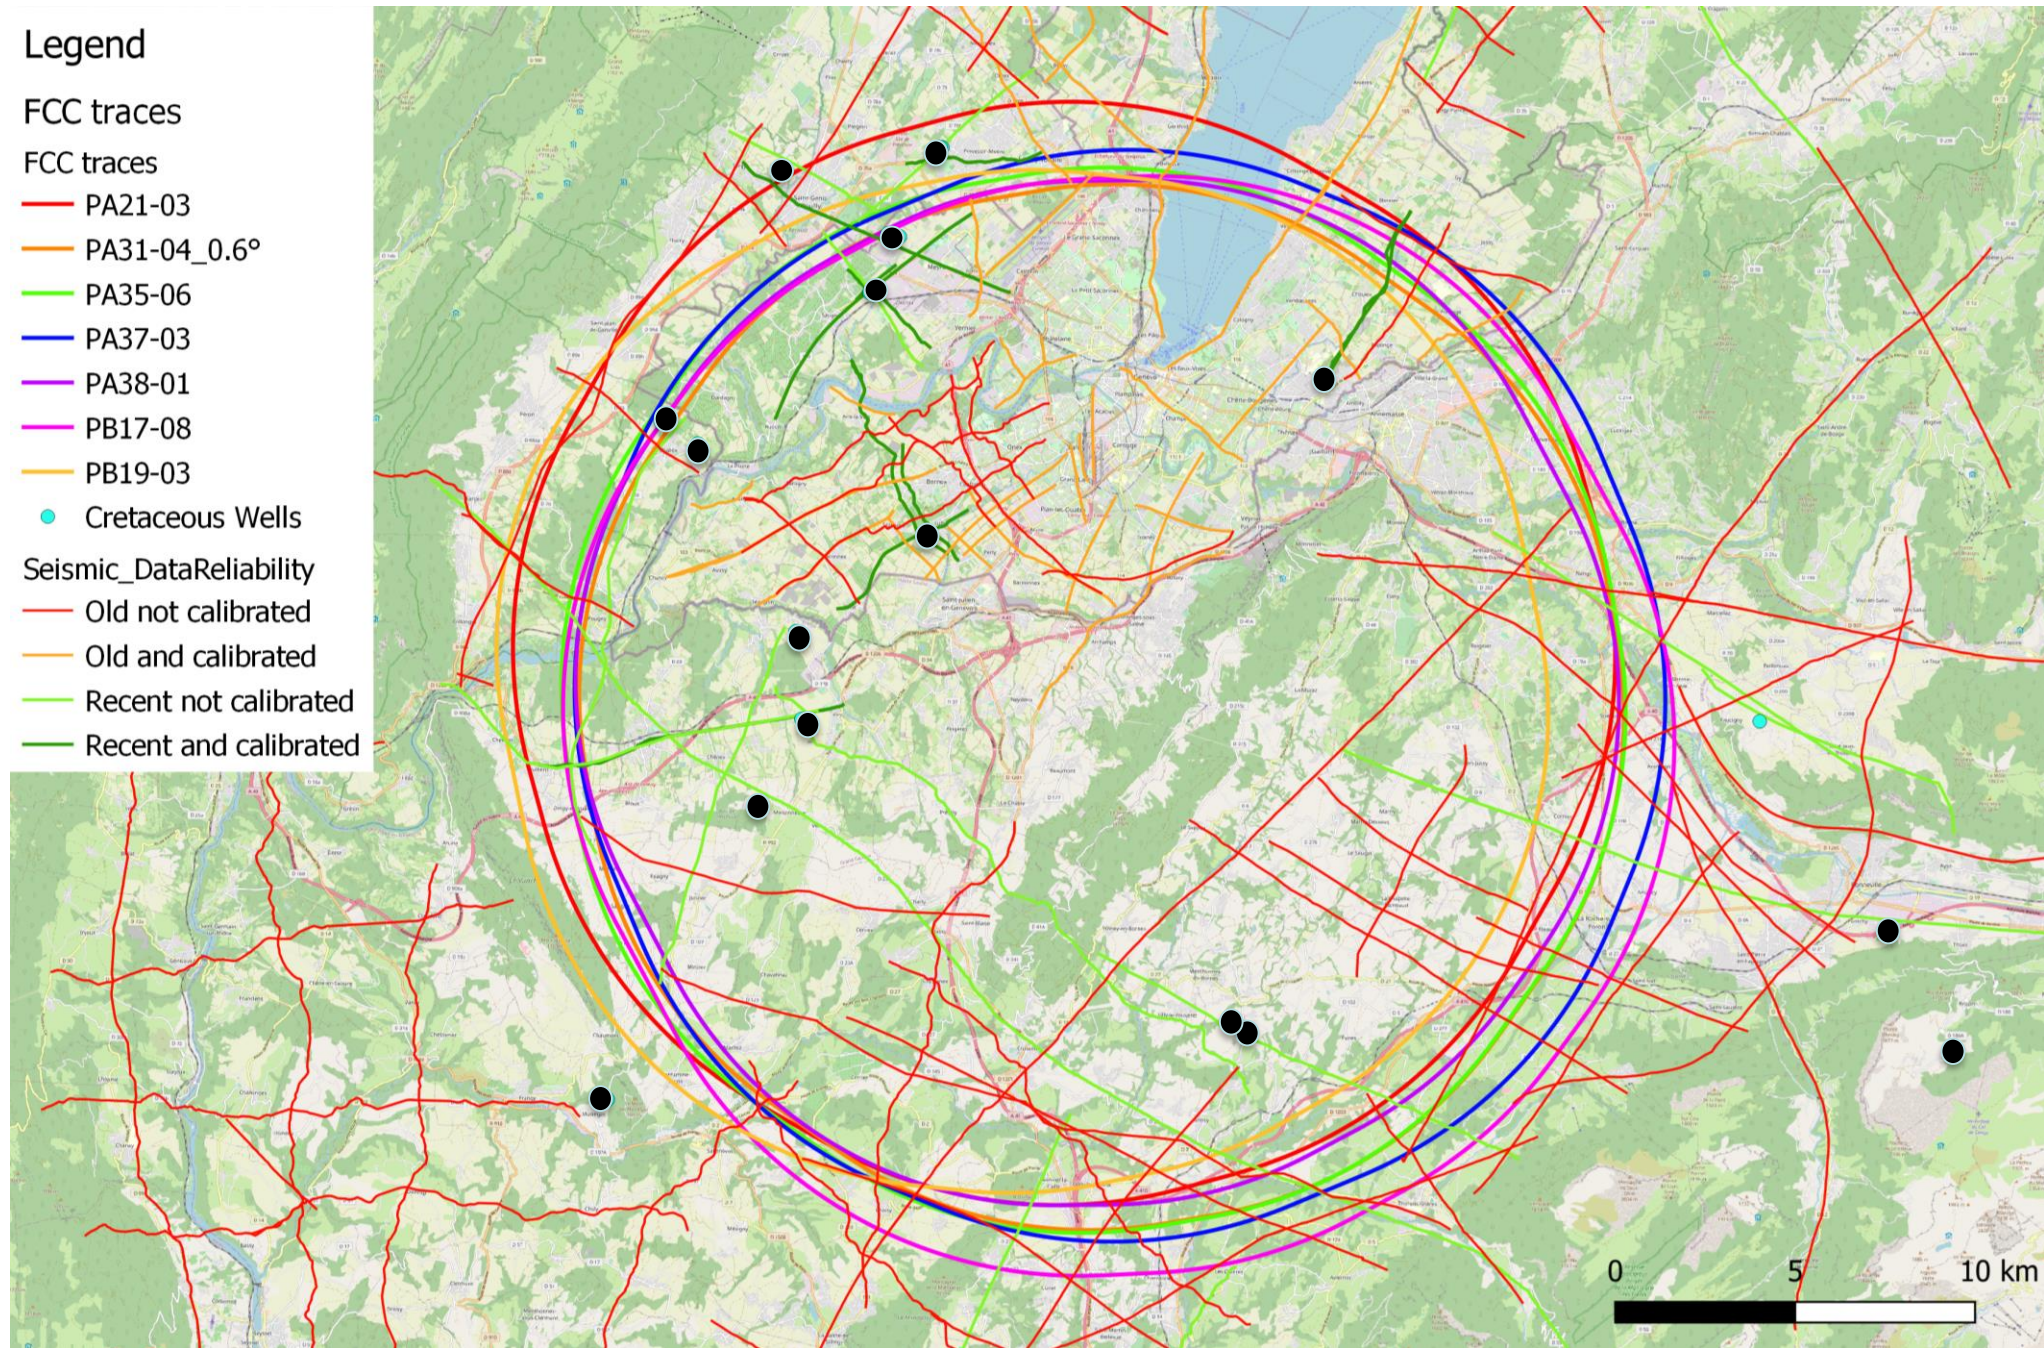

Data reliability along the FCC trace:

- Top **Molasse well** data points
- Strong well control in Geneva area compared to Bornes Plateau.

Data reliability along the FCC trace:

- Cretaceous Limestones data points
- 2D seismic data are key

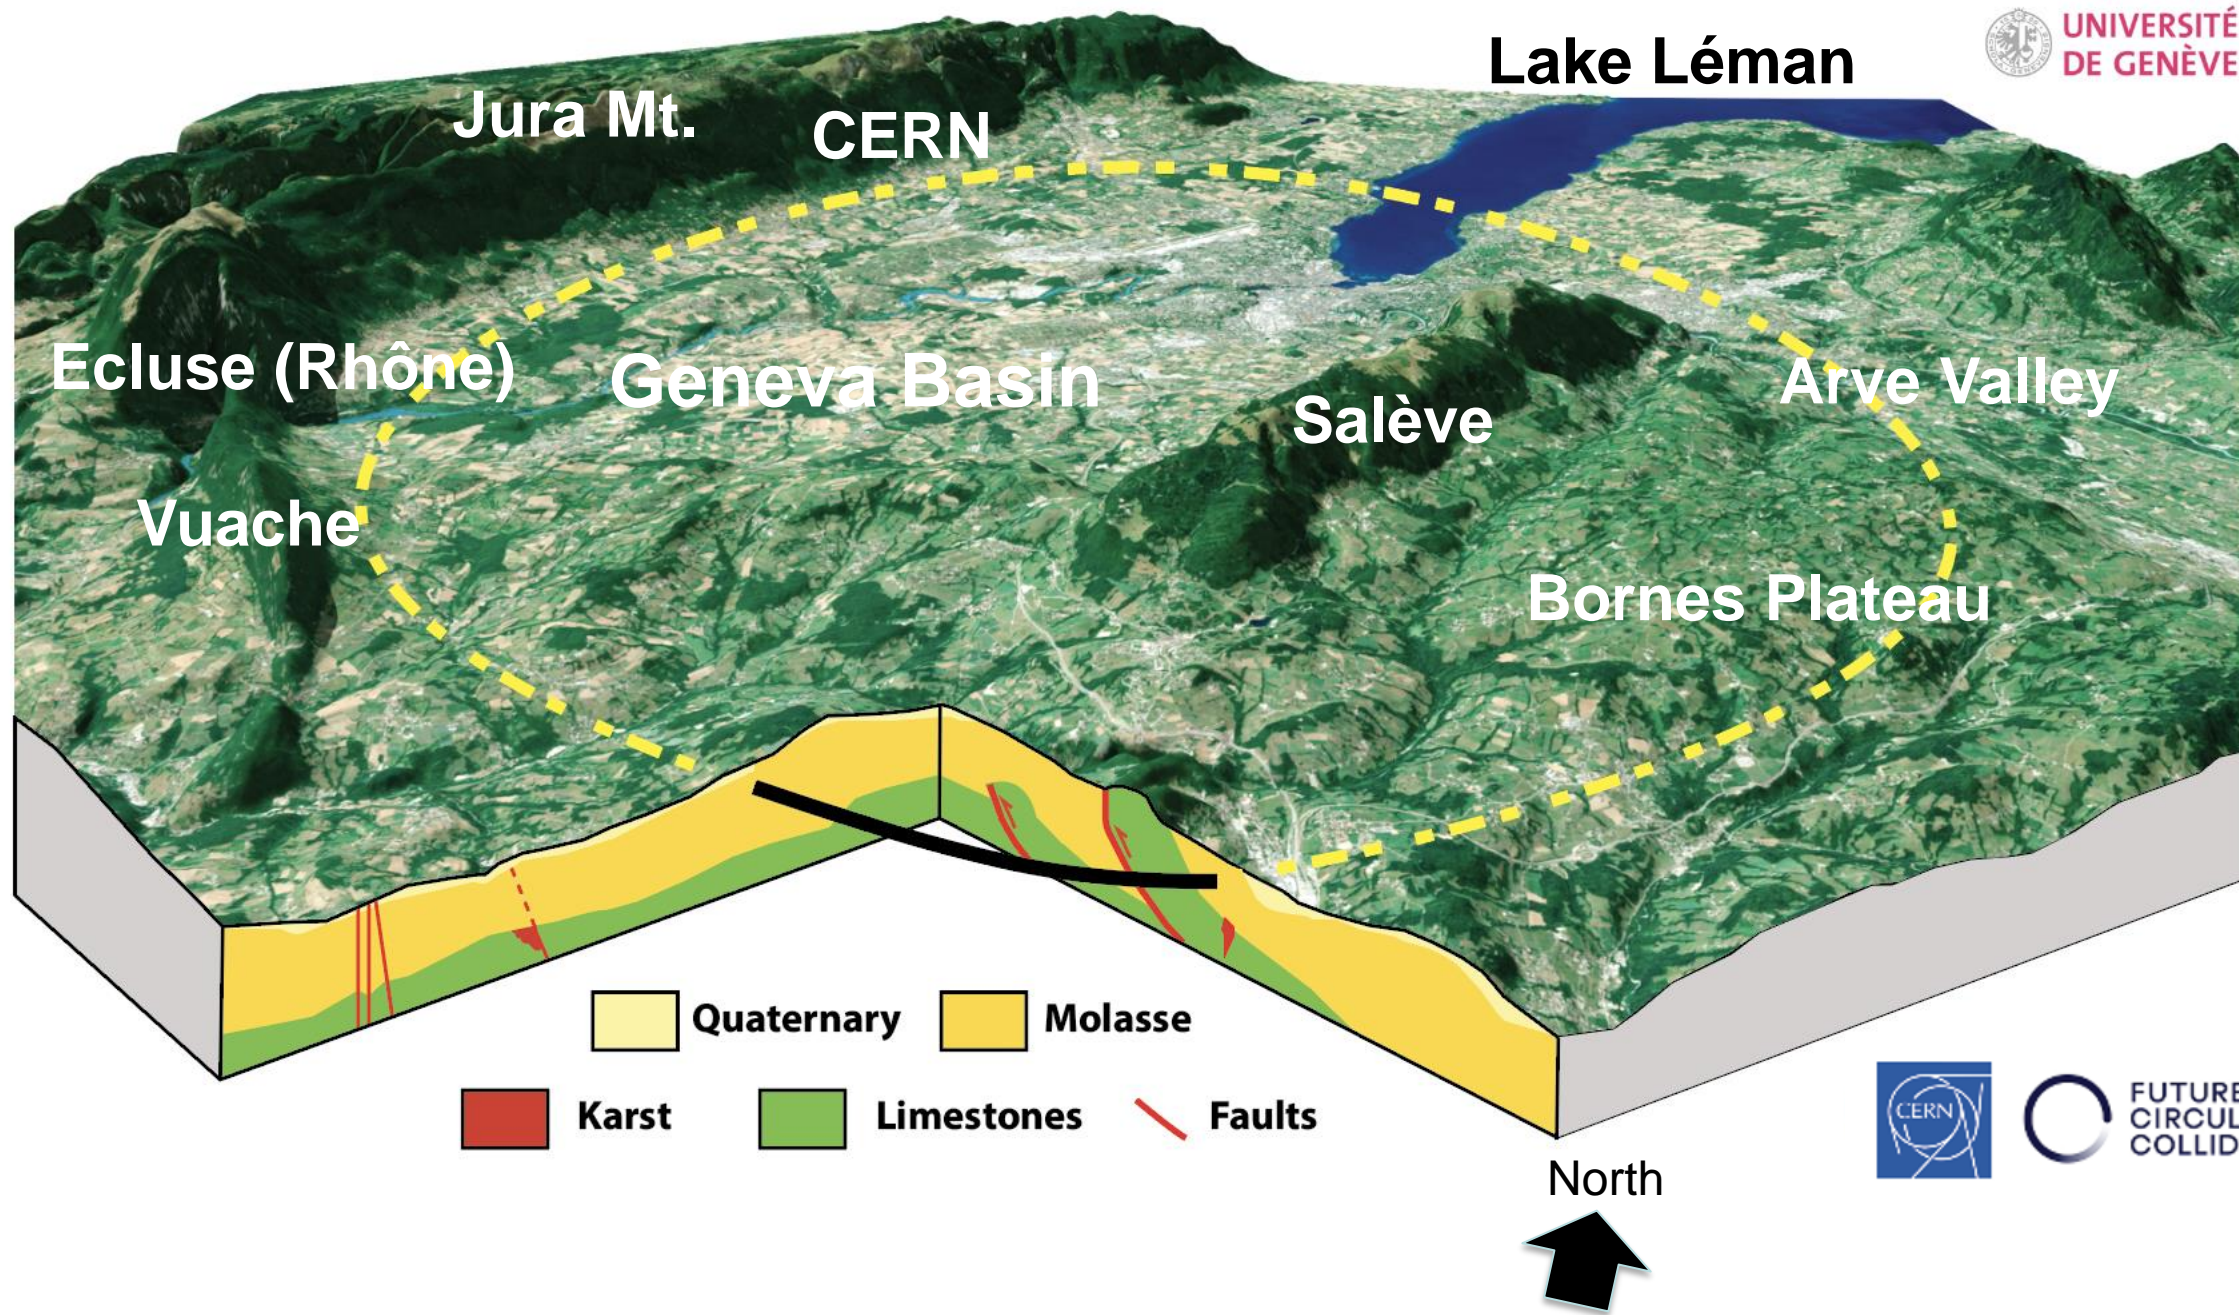

3D GEOLOGICAL MODEL

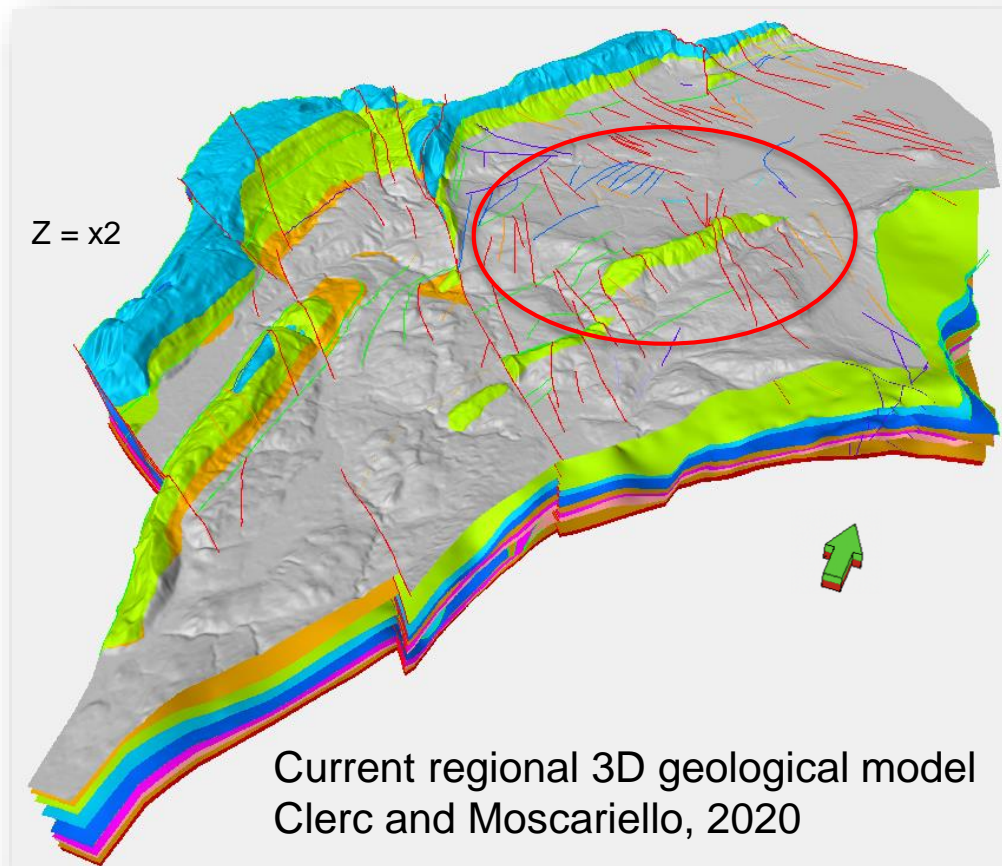

a CERN FCC- UNIGE joint project

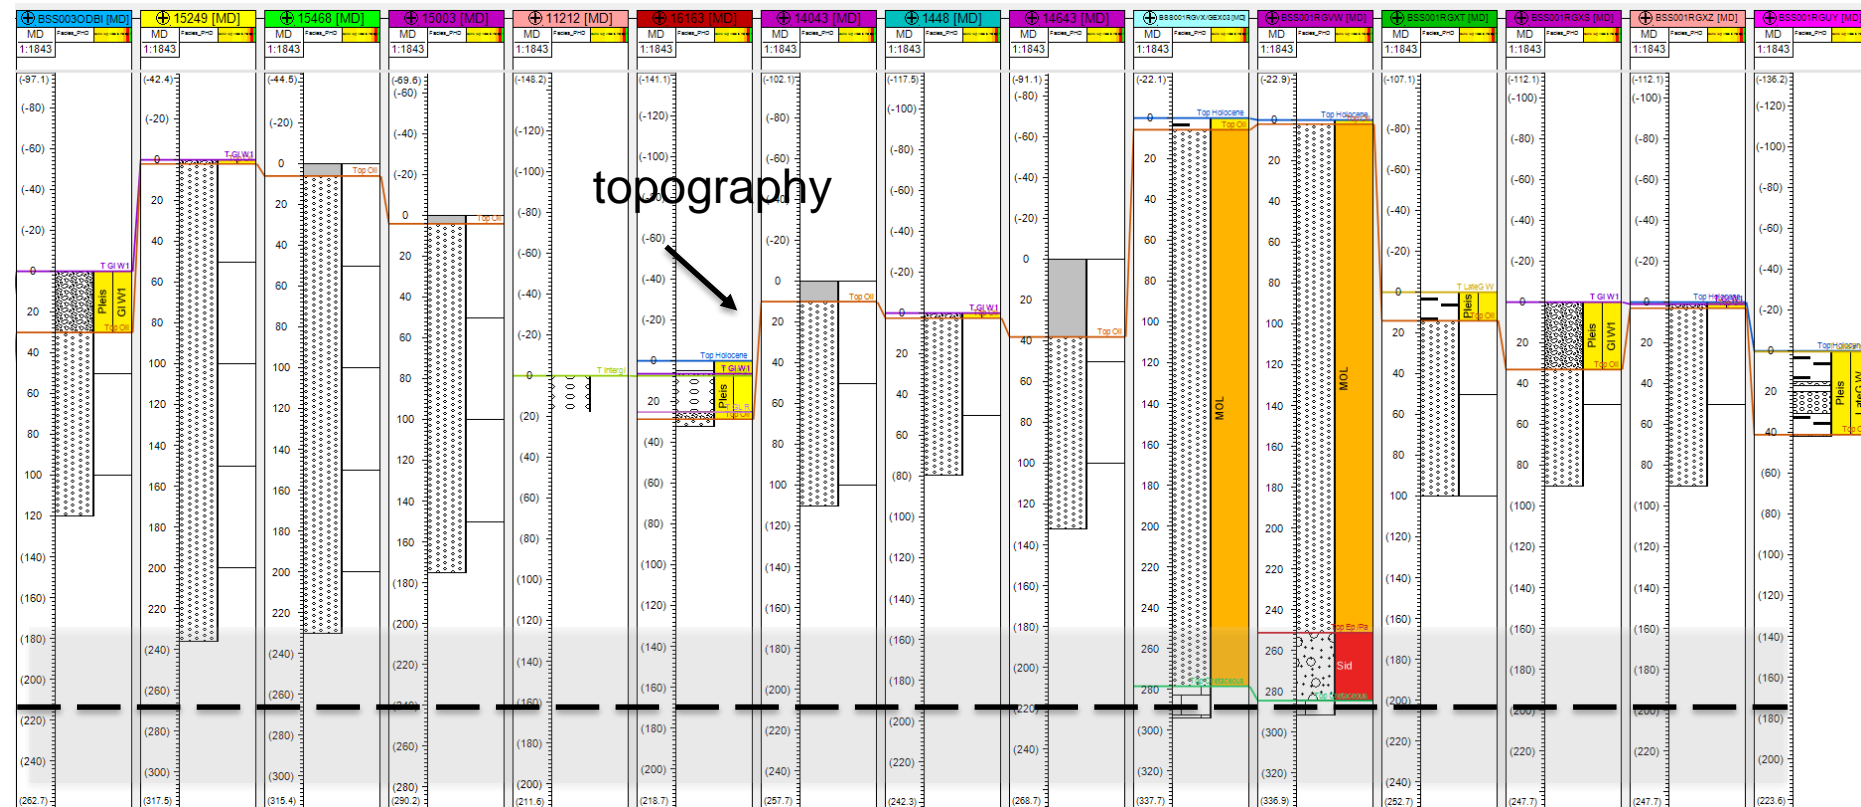

3D Modelling: Focus on a 4 km wide belt along the FCC trace

JURA area

2 Key surfaces in the 3D geological model

Mostly based on boreholes interpolation. High uncertainties when based on seismic only.

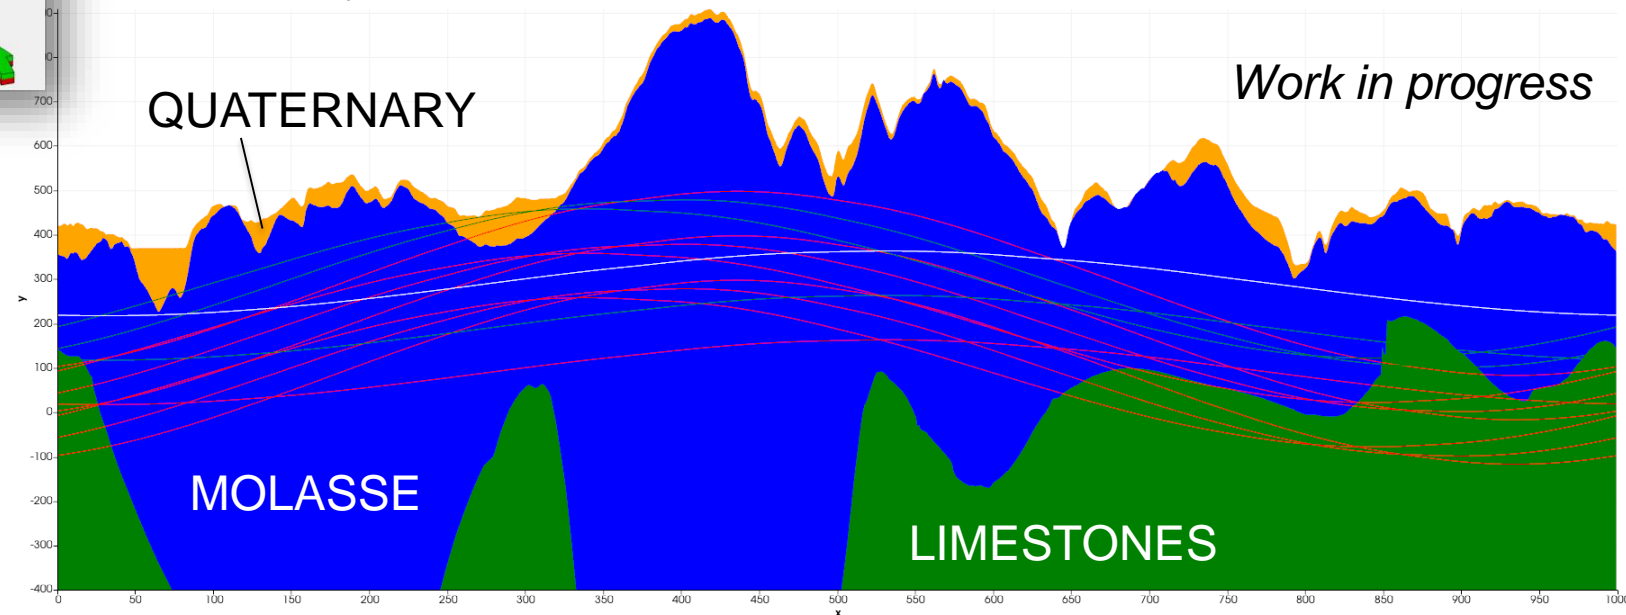

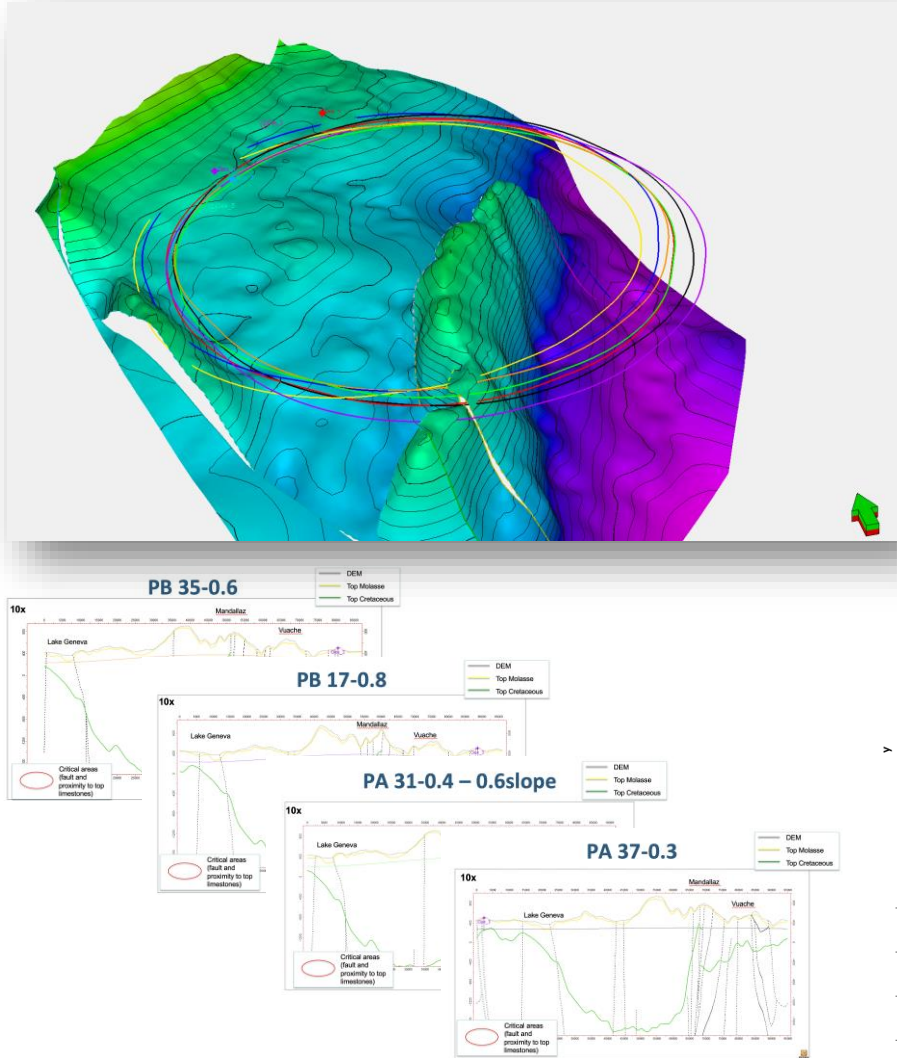

Interpolated and depth-converted top limestones (Cretaceous) layer. Mostly based on 2D seismic due to few borehole penetrations.

FCC trajectory sensitivity tests

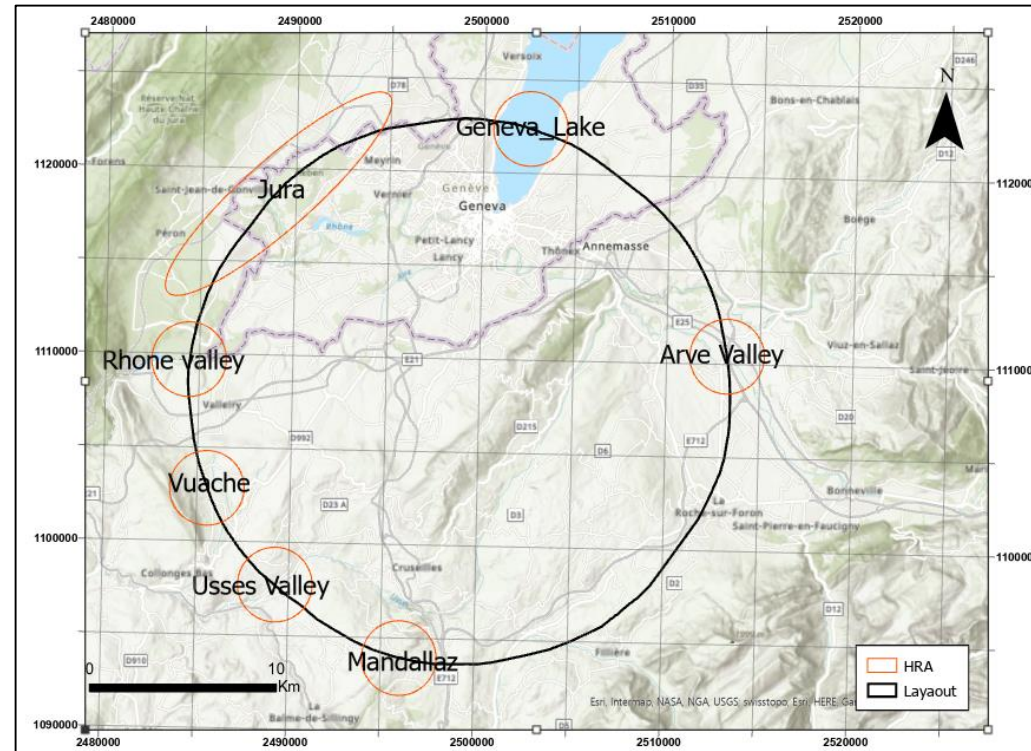

7 different trajectories have been evaluated and geological uncertainties/risks identified and assessed.

This led to the selection of a trajectory (31.10):
Azimuth, inclination and rotation of the FCC ring is tested and geological parameters extracted (depth from surface, thickness Quaternary, Molasse, depth Limestones, etc).

Conclusions

- The FCC data base has been completed and will serve as the basis for future engineering planning work
- 3D geological model to date provides a **solid knowledge framework** based on all available data known to date, highlighting the different lithological and structural heterogeneities crossed by the planned trace of the FCC tunnel.
- The model allows the **visualisation of the subsurface conditions** known to date in the areas of high geological uncertainty identified **enabling to take informed decisions during the forthcoming geotechnical and seismic investigation campaign** which will take place across the French and Swiss border.

Perspectives

- FCC subsurface data base will be managed by UNIGE and updated with new information acquired over the years to come
- Following this investigation campaign, the geological 3D model will be updated with the new acquired data and will therefore provide more accurate view of the subsurface.
- This 3D model represents therefore a practical working tool which will support the FCC project throughout the different phases of tunnelling design, planning and execution.

- Thank you for your attention and financial support !
