

Update muX meeting 12/07

Michael Heines

Rerunning for gain drift

- Anticoincidence window adjusted to $1\mu\text{s}$ before the muon and $3\mu\text{s}$ after
→ Factor 2-2.5 increase in statistics for calibration lines for stable isotopes!
- Reran analyzer with $[-3; +1]\mu\text{s}$ anticoincidence window
- Gaindrifting: divide in 2 hour batches → Use moving average of 3 blocks

Rerunning for gain drift

- Anticoincidence window adjusted to $1\mu\text{s}$ before the muon and $3\mu\text{s}$ after
→ Factor 2-2.5 increase in statistics for calibration lines for stable isotopes!
- Reran analyzer with $[-3; +1]\mu\text{s}$ anticoincidence window

Do we increase bias?

Partially shared statistics \rightarrow Red line gives “allowed deviation”
Fitting process not exact, so slight deviations are possible

Rate decrease of muon capture lines

Gain drift – Same story, just more statistics

Gain drift – Same story, just more statistics

Ge06A still wonky during ^{40}K run; other Ge06 detectors quite ok

Gain drift – Same story, just more statistics

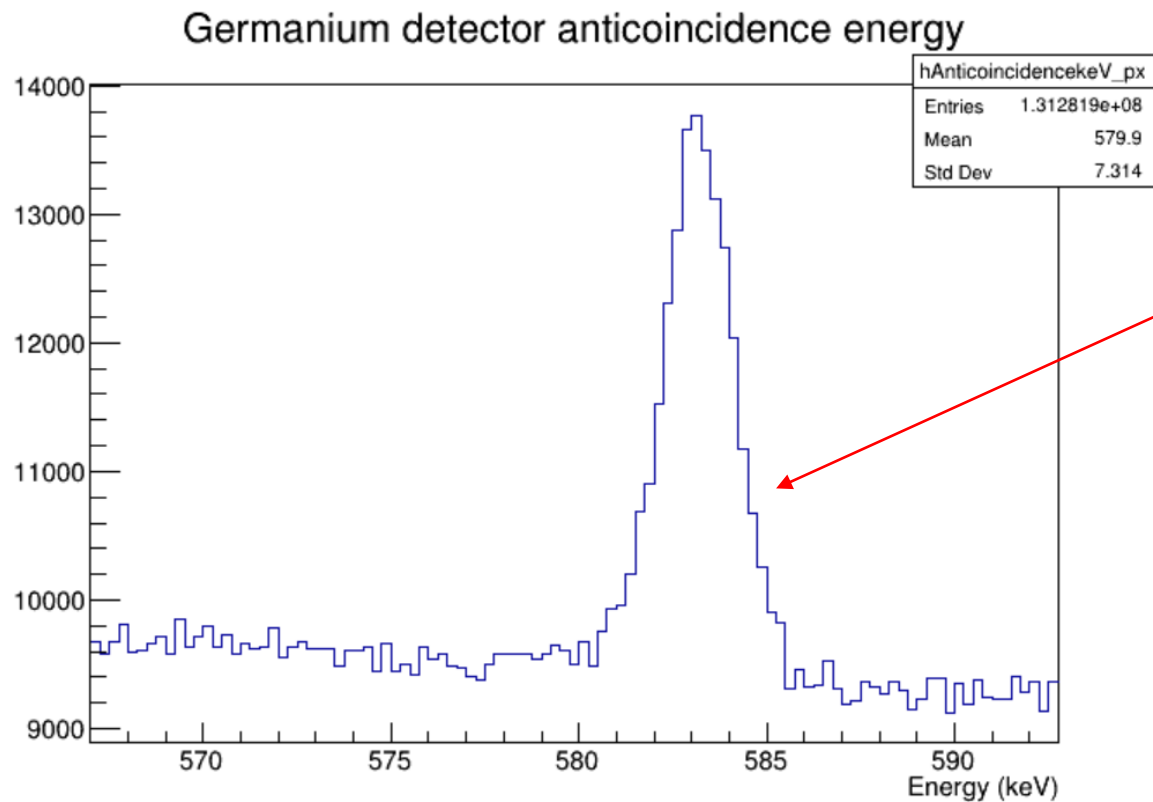

Ge06A still wonky during ^{40}K run; other Ge06 detectors quite ok

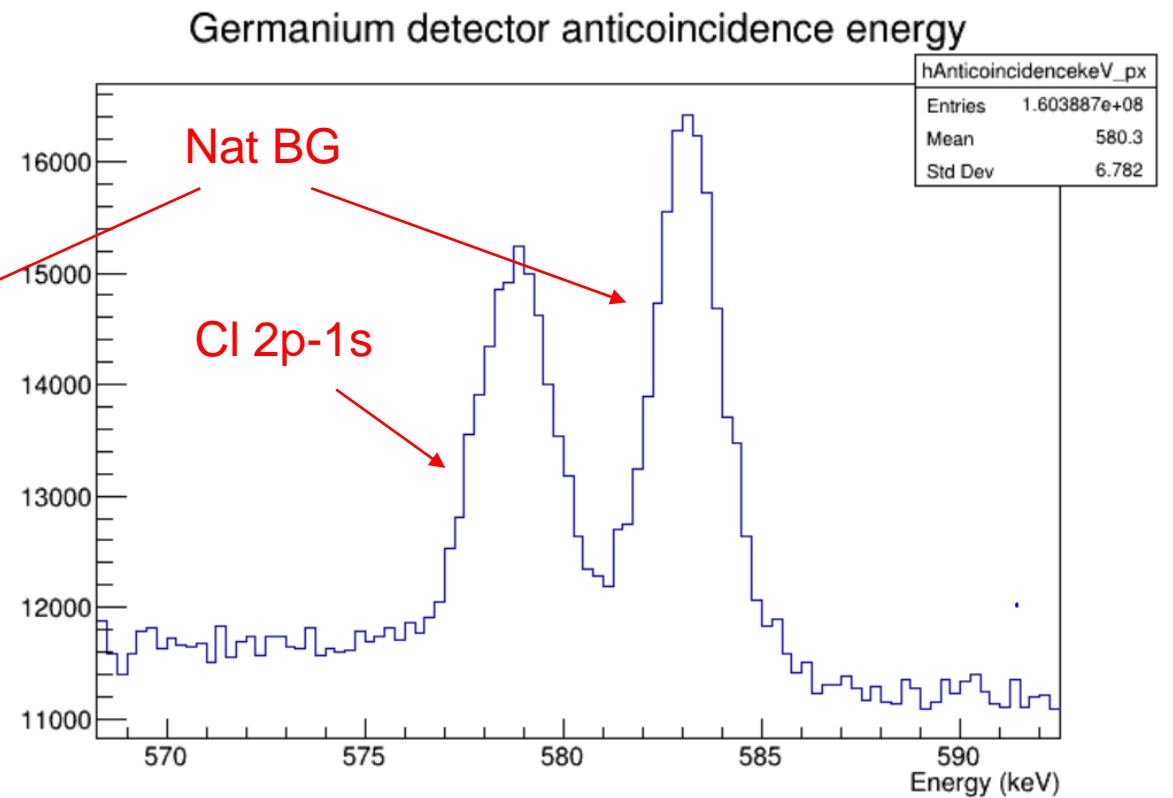

Nonlinearity seems to change, but at least it is consistent within an isotope!

One oddity...

- K-39[KCl] first part

- K-39[KCl] second part

One oddity...

- K-39[KCl] first part

- K-39[KCl] second part

Run right after K-41 [KCl]

Clean again? Only second K-39[KCl] run has remains of 2p-1s
→ In principle not an issue for calibration, but weird...

Germanium detector anticoincidence energy

Germanium detector anticoincidence energy

Still need to check if it is in a few runs (remove short bit of data) or in all runs of the second part (need to live with it)

Hypermet fitting - inputs

Literature values + errors

Fit centroids + errors

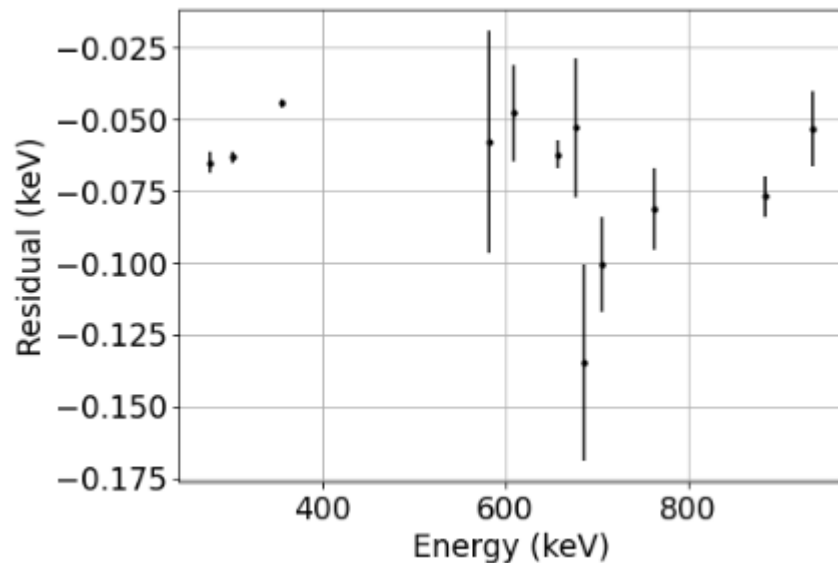

Line shape parameters + errors

Correlation between line shape parameters

→ Written to json for easier processing

Using outputs for recalibration

- Before correction: Offset likely due to change between hypermet and gaussian

- After: No more offset, nice energy precision!

Data for Ge02 (95% REGe) on 1 shift of statistics → Can still benefit from increase in statistics!

How to estimate error on calibration - Bootstrapping

Example of **non-parametric resampling**: draw randomly with replacement

original dataset = {1.2, 4.8, 2.3, 2.1, 7.9, 10.0, 0.5, 5.6, 9.2, 1.1} N = 10

Resampled dataset \mathcal{X}_1^* = {1.2, 2.1, 9.2, 5.6, 0.5, 2.3, 9.2, 0.5, 1.1, 0.5} N = 10

Resampled dataset \mathcal{X}_2^* = {9.2, 0.5, 10., 2.3, 2.1, 7.9, 2.1, 4.8, 5.6, 1.2} N = 10

⋮

⋮

Resampled dataset \mathcal{X}_M^* = {2.1, 10., 1.2, 0.5, 7.9, 1.1, 7.9, 1.2, 5.6, 10.} N = 10

Some values occur multiple times

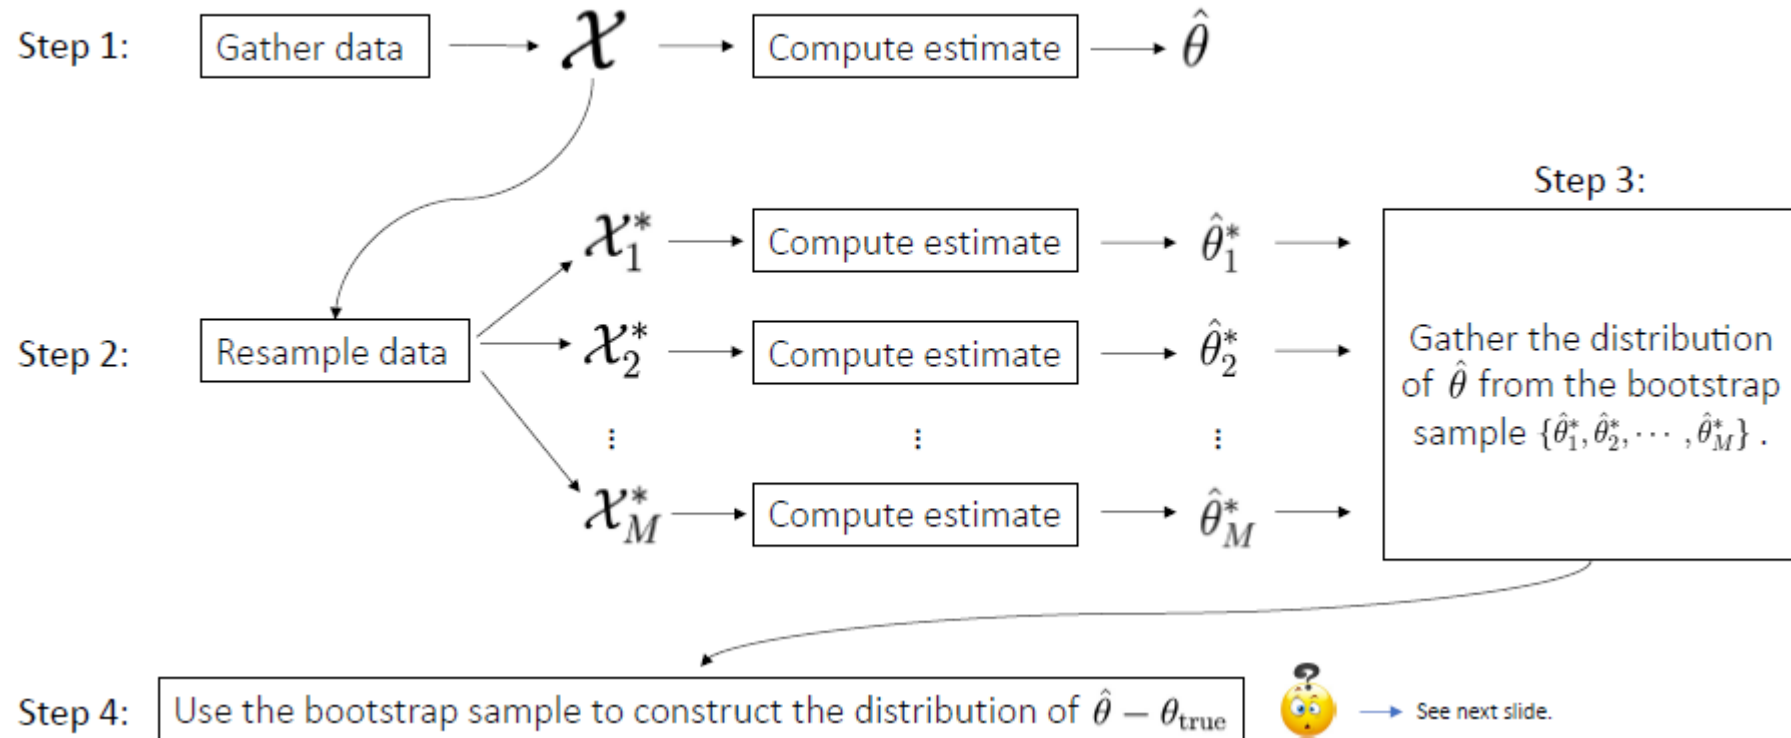

Other values (e.g. 4.8) don't occur at all in dataset #M

The total size of the dataset
always stays the same.

How to estimate error on calibration - Bootstrapping

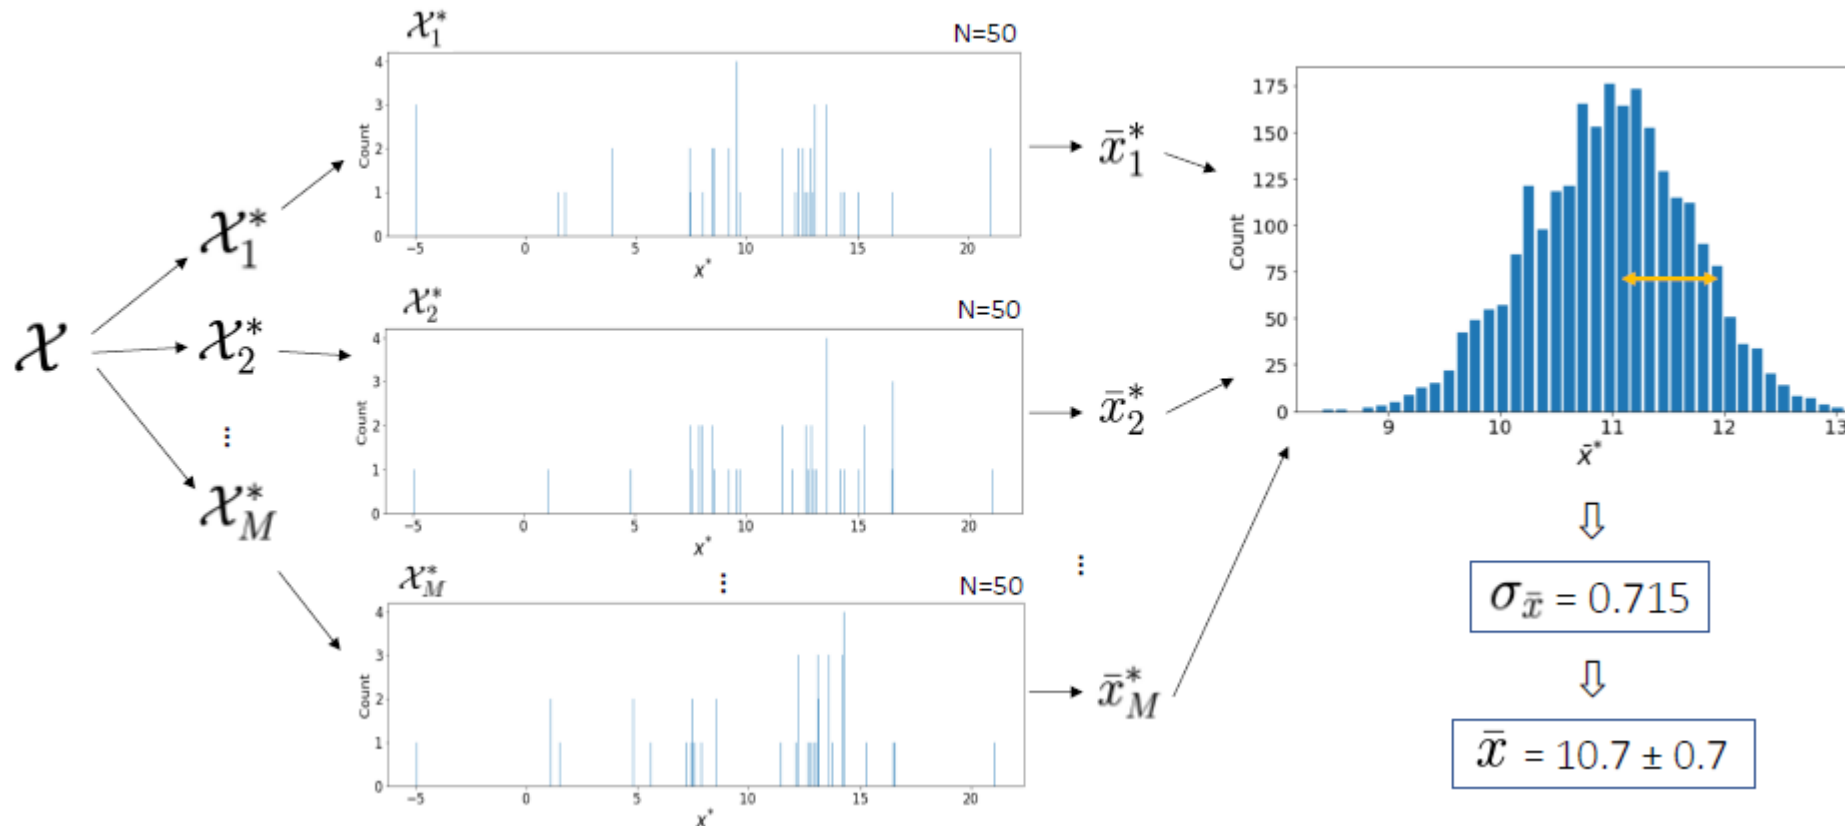

The general principle of non-parametric bootstrapping:

Slide courtesy: Joris de Ridder

How to estimate error on calibration - Bootstrapping

- Resampled datasets (with replacement):

Slide courtesy: Joris de Ridder

How to estimate error on calibration - Bootstrapping

- General idea:
 - Perform many fits
 - Look at distribution of results
- My extra constraints:
 - At least 1/3 points below 400 keV
 - At least 1/2 points above 800 keV

Preliminary on Ge02: Seems to work well

How to estimate error on calibration - Bootstrapping

- General idea:
 - Perform many fits
 - Look at distribution of results
- My extra constraints:
 - At least 1/3 points below 400 keV
 - At least 1/2 points above 800 keV

Preliminary on Ge01: 1σ alright, 2σ weird

How to estimate error on calibration - Bootstrapping

- General idea:
 - Perform many fits
 - Look at distribution of results
- My extra constraints:
 - At least 1/3 points below 400 keV
 - At least 1/2 points above 800 keV

Preliminary on Ge05: Not sure, more stats would be good

What's next

- Rerun analyzer with gain drift correction
 - Anticoincidence trees → Spectra → Hypermet fitting → Calibration
 - Veto, pile-up, ... cuts
- Calibration fit using ODR rather than regular fit with $y\text{-error} = x\text{-error} + y\text{-error}$ to see if anything changes
- Crosscheck calibration without known line (707 keV, 583 keV), check how much a weighted average deviates from literature
- Fit np-1s lines

Update from theory side

- Contacted Paul Indelicato for QED calculations → Awaiting response
- Contacted Karim Bennaceur for charge density calculations (V2 correction)
 - His methods work best for even-even
 - K and Cl rather spherical, so he can do mean-field approximation
 - Still things to implement in his code, but thinks he could get results by end of August!
- Backup/Simple calculation NP? Ben mentioned he knows someone in Mainz who might be able to help
