## A Torsion Pendulum Based Axion Search

*Monday, 11 October 2010 15:50 (20 minutes)*

Despite two decades of experimental effort, the elusive axion has yet to be found. Nevertheless, for possible axion masses between  $10^{-7}\mu\text{eV}$  and  $10^{-5}\text{meV}$ , it remains a well motivated solution to the strong CP problem, and a promising dark matter candidate. Current searches use the axion-two-photon coupling to probe for axions that could be generated in the sun, remnants from the big-bang or created in the laboratory. Using techniques inspired by torsion pendulum based tests of gravity, we have constructed a new torsion pendulum experiment that looks for a macroscopic parity and time violating force mediated by virtual axions. For an axion mass of  $1^{-5}\text{meV}$ , we have improved the limit on this force by ten orders of magnitude. In addition, we have demonstrated that one can operate a torsion pendulum in a strong magnetic field, and thus, have opened another path to look for very heavy axions.
