## **Decay of the free neutron**

e  $\beta - \nu$  correlation in neutron decay n  $\rightarrow$  (p)+ e⁻ + ⊽  $\overline{v}_{a}$ W Mixed Fermi and Gamow Teller decay. Differential neutron decay probability:  $dW \propto \rho(E_{\rm e}) \cdot \left\{ 1 + \frac{\vec{p}_{\rm e} \cdot \vec{p}_{\nu}}{E_{\rm e}E_{\rm e}} + \frac{m_{\rm e}}{E_{\rm e}} \right\}$  $+ \left( A \frac{\vec{p}_{e}}{E_{e}} + B \frac{\vec{p}_{v}}{E_{v}} + D \frac{\vec{p}_{e} \times \vec{p}_{v}}{E_{e}E_{v}} + \dots + R \frac{\vec{p}_{e} \times \vec{\sigma}_{e}}{E_{e}} \right) \cdot \vec{\sigma}_{n} \right\}$ -1.250Measurements of A Measurements of *a* ftom neutron beta decay -1.260 -1.265 -1.270 -1.270 -1.275 -1.255  $\left| a = \frac{1 - \left| \lambda \right|^2}{1 + 3 \left| \lambda \right|^2} \right| \quad A = -2 \frac{\left| \lambda \right|^2 + \left| \lambda \right| \cos \phi}{1 + 3 \left| \lambda \right|^2}$ -1.260--1.265 -1.270 λ=-1.2695(29) from PDG2008 Accuracy of best  $\lambda = |g_{\rm A}/g_{\rm V}|e^{i\phi}$ previous experiments:  $\Delta a / a \sim 5\%$ aliminary Our final aim:  $\Delta a/a \sim 0.3\%$ Verozolinski, 1991 PERKEO II. 2002 PERKEO 11, 2008 PERKEO II. 1991 UCNA.2009 Stratona, 1978 -1.280 PERKEO, 1986 Liaud, 1997

For the physics see e.g. H. Abele, Prog. Part. Nucl. Phys. 60 (2008) 1

**Experimental principle** 

Measurement of the  $\beta$ -v angular correlation via the energy spectrum of the decay protons

JOHANNES GUTENBERG

## **Overview aSPECT**

#### Schematic and set-up at ILL

PSI Workshop 2013

## Recoil energy spectrum 2008

The systematic errors have to be understood.

# A new beamtime of ~100 days has just been completed successfully at the cold neutron beam line PF1B at ILL!

M. Beck

JOHANNES GUTENBERG

PSI Workshop 2013

#### Major systematic uncertainties at *a*SPECT are:

- The stability and homogeneity of the retardation potential Required for  $\Delta a/a = 0.3\%$ : 10 mV
- The field ratio  $r_{_{\rm R}}$  of the magnetic fields in the DV and AP

Required for  $\Delta a/a = 0.3\%$ :  $\Delta r_{_B}/r_{_B} = 1e-4$  (absolute, stability)

- Retardation voltage dependent background Should be < 0.1 1/s
- A saturation effect of the detector electronics observed in 2008 Increased the error on small a to  $\Delta a/a > 10\%$
- Discharges due to trapped particles observed in 2011 Have to be absent

#### $\rightarrow$ All of these have to be checked experimentally!

For details and other systematics based on the analysis of a beam time in 2008 see
M. Simson, PhD thesis, ILL 2009
M. Borg, PhD thesis, Mainz 2010
G. Konrad, PhD thesis, Mainz 2011
F. Ayala Guardia, PhD thesis, Mainz 2011

## **Essential Improvements**

#### Modified detector electronics

#### Preamplifier with reduced amplification

#### New shaper with

- proton-electron separation
- log amplification for large signals

Shaper tests with pulser, 16.7.2011

M. Beck

PSI Workshop 2013

#### Modified detector electronics

Saturation effect visible in the pulseheight spectrum of the detector for short time differences between correlated electron and proton events

2008: Protons shortly after electron events are lost (black) or show reduced pulse heights (blue) 2013: The same protons show normal pulse height distribution

#### $\rightarrow$ Saturation problem of the detector electronics solved.

M. Beck

PSI Workshop 2013

![](_page_8_Picture_0.jpeg)

![](_page_8_Picture_2.jpeg)

#### Electrode system

- Goal: Well-defined potentials  $\rightarrow$  New DV and AP electrodes
- Goal Eliminate/reduce discharges Reduce the background due to field emission/trapped particles
- $\rightarrow$  Improved vacuum
- → Remove edges/any sharp points/rough surfaces

Several electrodes made newly All electrodes checked for edges, etc. New Au-coating for many electrodes (DV and all AP electrodes) Has to be redone before every beam time! (degrades within one year, costly) → Electrode above AP electrode changed to a dipole electrode

To remove trapped particles by the ExB drift

**Essential Improvements** 

### New decay volume and analyzing plane electrode

PSI Workshop 2013

#### Flat surfaces

JOHANNES GUTENBERG **UNIV/FRSITÄT** 

- $\rightarrow$  well defined surface properties
- $\rightarrow$  work function can be measured easily
- See poster by Ch. Schmidt

![](_page_9_Figure_8.jpeg)

![](_page_9_Picture_9.jpeg)

![](_page_10_Picture_0.jpeg)

![](_page_10_Picture_2.jpeg)

#### New decay volume and analyzing plane electrode

![](_page_10_Picture_4.jpeg)

![](_page_10_Picture_5.jpeg)

 $1~\mu m$  Au on 10  $\mu m$  Ag on a smoothly polished Cu-surface

![](_page_11_Picture_0.jpeg)

![](_page_11_Picture_2.jpeg)

#### Electrode system

- Goal: Well-defined potentials  $\rightarrow$  New DV and AP electrodes
- Goal Eliminate/reduce discharges Reduce the background due to field emission/trapped particles
- $\rightarrow$  Improved vacuum
- → Remove edges/any sharp points/rough surfaces

Several electrodes made newly All electrodes checked for edges, etc. New Au-coating for many electrodes (DV and all AP electrodes) Has to be redone before every beam time! (degrades within one year, costly) → Electrode above AP electrode changed to a dipole electrode

To remove trapped particles by the ExB drift

![](_page_12_Picture_0.jpeg)

## The beamtime

![](_page_12_Picture_2.jpeg)

The background at *a*SPECT consists of several components with potentially different dependence on the AP potential.

![](_page_12_Figure_4.jpeg)

![](_page_13_Picture_0.jpeg)

## **Essential Improvements**

![](_page_13_Picture_2.jpeg)

![](_page_13_Picture_3.jpeg)

PSI Workshop 2013

![](_page_14_Picture_0.jpeg)

![](_page_14_Picture_2.jpeg)

There were many other improvements, e.g.

#### Improved vacuum

Cascaded turbopumps, additional NEG pump, improved cleaning procedures

## New **beam collimation** inside *a*SPECT

Conductive to avoid field leakage into the decay volume

#### Monitoring of the **B-field** of aSPECT on the outside using Hall probes Check of the field stability

#### New NMR

Determination of the absolute B-field and the field ration of AP and DV at the level of 10<sup>-5</sup>

Measurement of the work function of the electrodes using a Kelvin probe Important for the determination of the retardation potential and several other syst. effects

#### Measurement of the **beam profile** directly inside the DV

#### And more ...

![](_page_15_Picture_0.jpeg)

![](_page_15_Picture_2.jpeg)

#### Beam time successfully completed

After initial checks and tuning: Data taking for small a and for systematic investigations:

1 day of data  $\leftrightarrow \Delta a/a \sim 2\%$ , typical length of one data set 2-3 days

→ Systematic investigations for different conditions with the full statistics

2 different detector electronics → See poster R. Virot
 Different background conditions → See poster R. Maisonobe (E15 dipole on/off, different focussing on the detector)
 2 different beam profiles
 Check of field leakage into the DV
 Emphasis on the understanding of the background.
 (variable component and retardation voltage dependence).

No catastrophic systematic effect observed. The data look good!

![](_page_16_Picture_0.jpeg)

![](_page_16_Picture_2.jpeg)

Several support measurements are ongoing

- Measurement of the work function of the DV and AP electrodes used.
- Measurement of the **magnetic field** with an NMR system (absolute values, ratio, stability).
- Detailed test measurements with the **preamplifier and shaper** used.
- Check of the calibration of the Hall probe and Agilent DVM.

Detailed analysis with quantitative determination of the systematic uncertainties, including simulations.

See poster A. Wunderle

We expect a total systematic uncertainty of  $\Delta a/a \sim 1-2\%$ 

![](_page_17_Picture_0.jpeg)
