

# A New Search for Neutron-Anti-Neutron Oscillations

## Neutron-Anti-Neutron Oscillations at ESS

12-13 June 2014, CERN, Geneva, Switzerland

Neutral particle oscillations have proven to be extremely valuable probes of fundamental physics. Kaon oscillations provided us with our first insight into CP-violation, fast Bs oscillations provided the first indication that the top quark is extremely heavy, B oscillations form the most fertile ground for the continued study of CP-violation, and neutrino oscillations suggest the existence of a new, important energy scale well below the GUT scale. Neutrons oscillating into antineutrons could offer a unique probe of baryon number violation.

The construction of the European Spallation Source in Lund, with first beam expected in 2019, together with modern neutron optical techniques, offers an opportunity to conduct an experiment with at least three orders of magnitude improvement in sensitivity to the neutron oscillation probability.

At this workshop the physics case for such an experiment will be discussed, together with the main experimental challenges and possible solutions. We hope the workshop will conclude with the first steps towards the formation of a collaboration to build and perform the experiment.

### Organising committee:

G. Brooijmans (Columbia University)  
S. Chattopadhyay (Cockcroft Institute)  
R. Hall-Wilton (European Spallation Source)  
Y. Kamyskov (University of Tennessee)  
E. Klinkby (Technical University of Denmark and European Spallation Source)  
M. Lindroos (European Spallation Source and Lund University)  
L. Mapelli (CERN)  
M. Mezzetto (INFN Padova)  
H. M. Shimizu (Nagoya University)  
W. M. Snow (Indiana University)  
T. Solder (Institut Laue Langevin)  
C. Thorne (European Spallation Source)

Register before  
19 May on  
[www.nnbar-at-ess.org](http://www.nnbar-at-ess.org)

**A. R. Young**  
NCSU

Thanks to G. Brooijmans for slides

PSI 2016  
PSI, October 17, 2016

# Outline

- Oscillations in Neutral Systems and B Violation
- Current Limits
- European Spallation Source
- Beamline & Detector Concepts
- Collaboration

# Central Questions for the Standard Model

Origin of neutrino mass

The cosmological baryon asymmetry

Pattern of charges and masses for the SM Fermions

Sources of Baryon Number Violation

**For example...**

**B-L Triangle:**

**All potentially connected by physics at or above EW scale**

Observable  $N - \bar{N}$  oscillations in a next generation experiment!

# Gaps in the Standard Model

## Many cosmological issues

- Dark matter and dark energy
- Not enough CP violation in the quark sector for baryogenesis
- Baryon number violation required for the baryon asym but where does it come from?

- Present in the SM through B-L (sphalerons)

→ Baryogenesis through leptogenesis and B-L?

Also find B violation in GUTs  
 $\Delta B=1$ : proton decay  $\rightarrow \Lambda > 10^{13}$  TeV

strong exptl limits...

$\Delta B=2$ : not constrained by p decay  
(wide range of scales for new physics...)

**produces oscillations!**

# The Power of Oscillations

- Neutral particle oscillations have played large role in particle physics
- $K^0$ - $\bar{K}^0$  oscillations ( $\Delta S = 2$ ) at the core of our initial understanding of CP-violation
- B meson oscillations ( $\Delta B = 2$ ):
  - Sensitive to CKM elements
  - CP-violation “workhorse”
  - Probe  $m_t^2/m_W^2$ 
    - First indication of large top mass! (1987)
- Sensitive probes of high mass

# Neutrino Oscillations

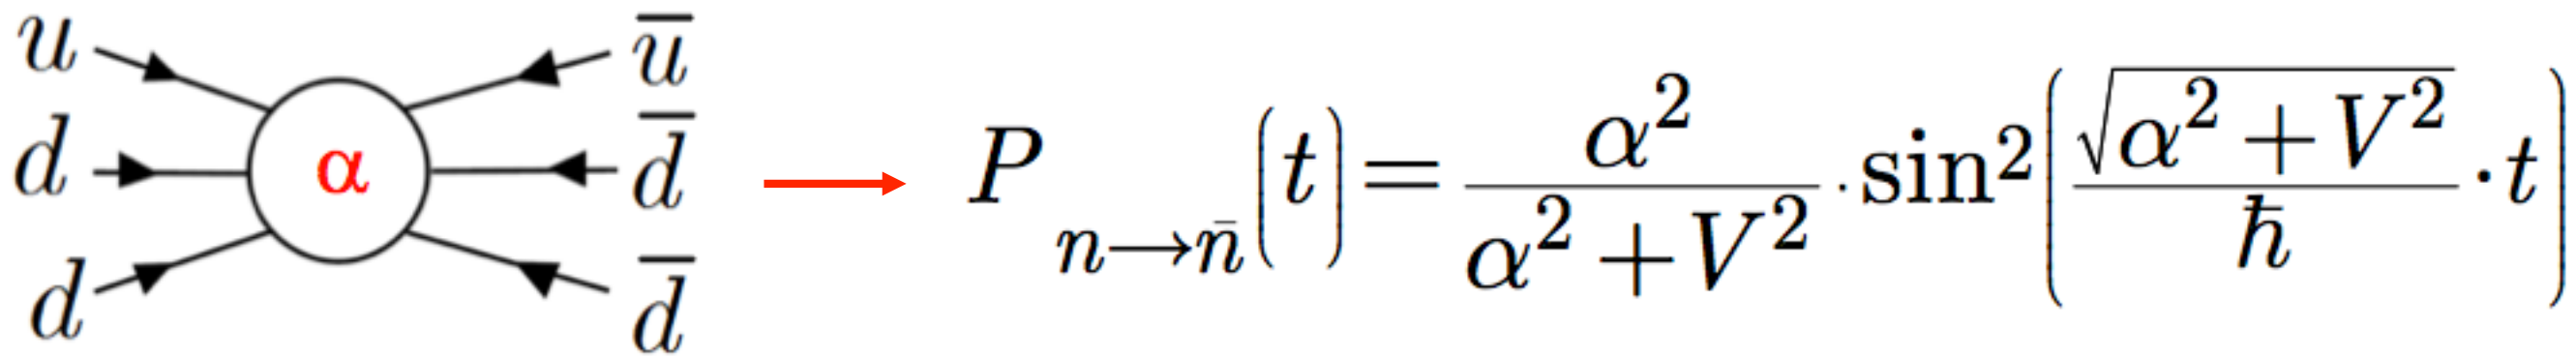

Neutrino oscillations unambiguously establish neutrinos are massive

- Since neutral, **Majorana** mass term allowed
- If exists,  $\Delta L = 2$ !
- If both Dirac and Majorana mass terms, mixing induces see-saw effect, *explaining* small neutrino masses
- Two scales: Dirac and Majorana mass terms
  - Lead to observed scales  $m_\nu \sim m_D^2/M$  and  $m_N \sim M$
- Dirac scale could be close to other fermions
  - Suggests a Majorana ( $\Delta L=2$ ) scale  $10^6 - 10^{10}$  GeV
- $\Delta B = 2$  at a similar energy scale?

# Experimental Aspects

# Process, Critical Parameters

- Potential  $V$  (if different for  $n$  vs  $\bar{n}$ )
  - Nuclear potential  $\sim 100$  MeV
  - $\mu_n \cdot B_{\text{Earth}} \sim 10^{-18}$  MeV
  - Current limit:  $\alpha < \sim 10^{-29}$  MeV (same order as nEDM)
- Strongly suppressed unless quasi-free condition holds ( $Vt/\hbar \ll 1$ )
  - Free neutron experiment requires substantial cancellation of Earth magnetic field, then:
  - For free neutron experiment, magnetic field can be used to check result if signal is seen
    - A few operators identified that allow oscillation with  $B$ , but not present in usual BSM physics

$$P_{n \rightarrow \bar{n}} = \left( \frac{\alpha}{\hbar} \times t \right)^2 = \left( \frac{t}{\tau_{n\bar{n}}} \right)^2$$

FOM:  $Nt^2$

[arXiv:1504.01176](https://arxiv.org/abs/1504.01176)

# Current Limits

Baldo-Ceolin et al, [Z.Phys. C63 \(1994\) 409-416](#)

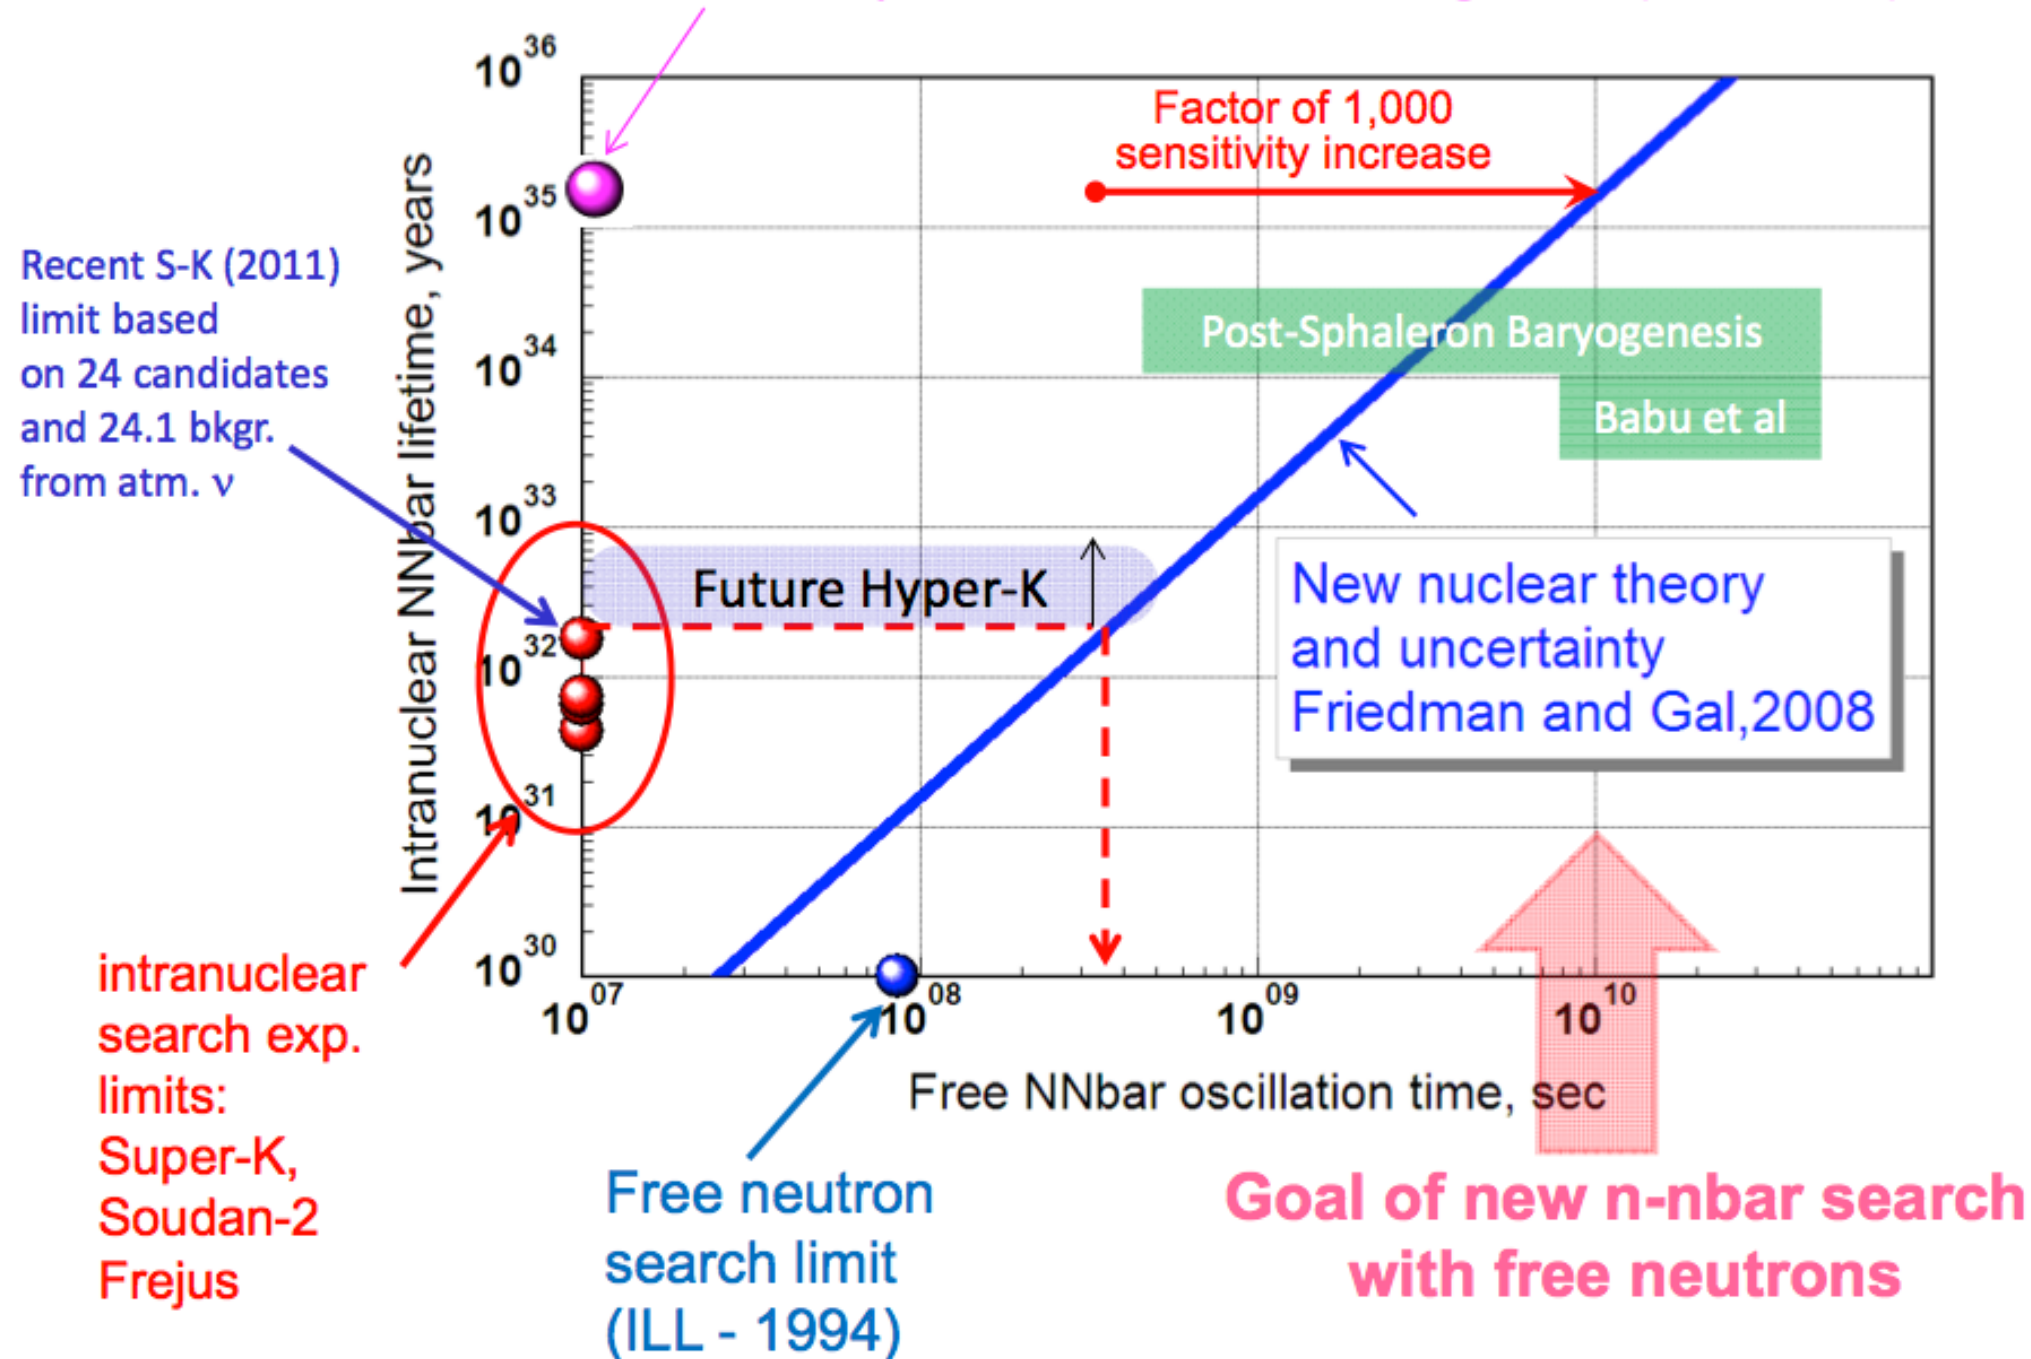

- $Nt^2 = 1.5 \cdot 10^9 \text{s}$ ,  $P < 1.6 \cdot 10^{-18}$  (run lasted  $\sim 1$  year) and  $\tau > 0.86 \cdot 10^8 \text{s}$
- Many subtle optimizations to minimize losses and backgrounds
- Experiment was background-free
- Bound neutron limits  $\sim 3$  times better
- But model-dependent, and now limited by atmospheric  $\nu$  background

$$\tau_{bound} = R \times \tau_{free}^2$$

# Free Neutron vs Bound Neutrons NNbar Search Sensitivity Comparison

$$R_{Ox} = 5 \times 10^{22} \text{ s}^{-1}$$

LBNE 35 kt, 10 years, if zero atm.  $\nu$  background (R&D issue)

**New physics could be enhanced or suppressed for bound neutrons**

# Next Generation Free Neutron Experiment

- Increase number of neutrons
  - Flux
    - Moderator brightness and area
  - Angular acceptance
  - Longer run
- Increase time-of-flight
  - Colder neutrons
  - Longer beamline
- Keep (or even increase) detection efficiency ( $\sim 50\%$ ), keep background at  $\sim 0$ 
  - Exploit current, established hardware and software technologies
- Better  $B_{\text{Earth}}$  suppression
  - Improved passive (+ active?) shield

# Next Generation Free Neutron Experiment

- Increase number of neutrons
  - Flux
    - Moderator brightness and area
  - Angular acceptance
  - Longer run
- Increase time-of-flight
  - Colder neutrons
  - Longer beamline
- Keep (or even increase) detection efficiency ( $\sim 50\%$ ), keep background at  $\sim 0$ 
  - Exploit current, established hardware and software technologies
- Better  $B_{\text{Earth}}$  suppression
  - Improved passive (+ active?) shield

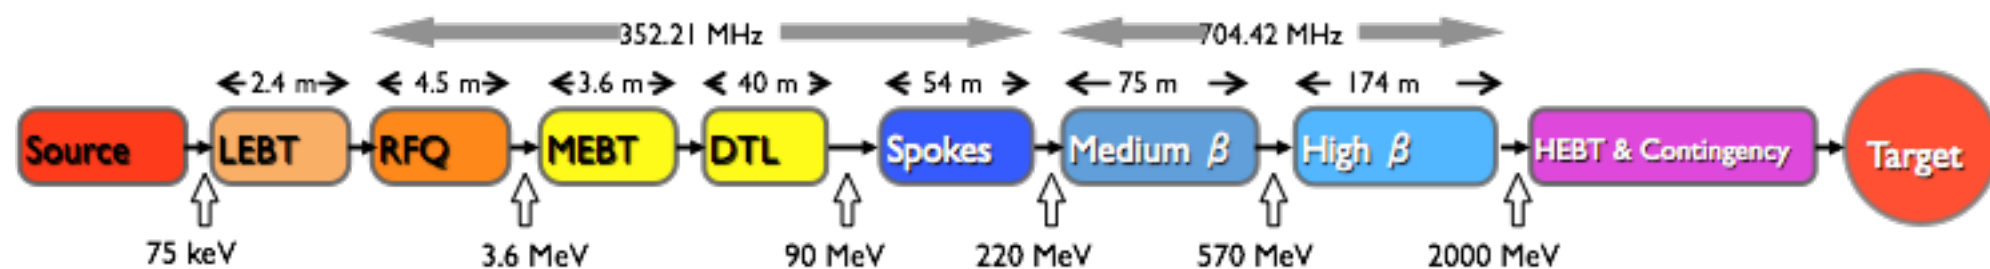

# European Spallation Source

Large beam port still in baseline!  
(details under discussion)

2.0 GeV superconducting linac, 14 Hz, 5 MW

# ESS Timeline

- 2014: ESS construction start
- 2019-2022: Initial phase: commissioning, intensity ramp, experiments by friendly users
  - **Experiment construction begins (first source recycle?)**
- 2023-2025: Initial user program operations: reliable operations with public users; establish basis for future cost sharing
  - **Experiment construction completion, commissioning, physics start**
- 2026+: routine operations, completion of final public instruments
  - **Physics run**

# Next Generation Free Neutron Experiment

- Increase number of neutrons
  - Flux
    - Moderator brightness and area
  - Angular acceptance
  - Longer run
- Increase time-of-flight
  - Colder neutrons
  - Longer beamline
- Keep (or even increase) detection efficiency (~50%), keep background at ~0
  - Exploit current, established hardware and software technologies
- Better  $B_{\text{Earth}}$  suppression
  - Improved passive (+ active) shield

# The Experiment

# Conceptual Design

See e.g. NNbarX (Babu et al.), <http://arxiv.org/abs/arXiv:1310.8593>

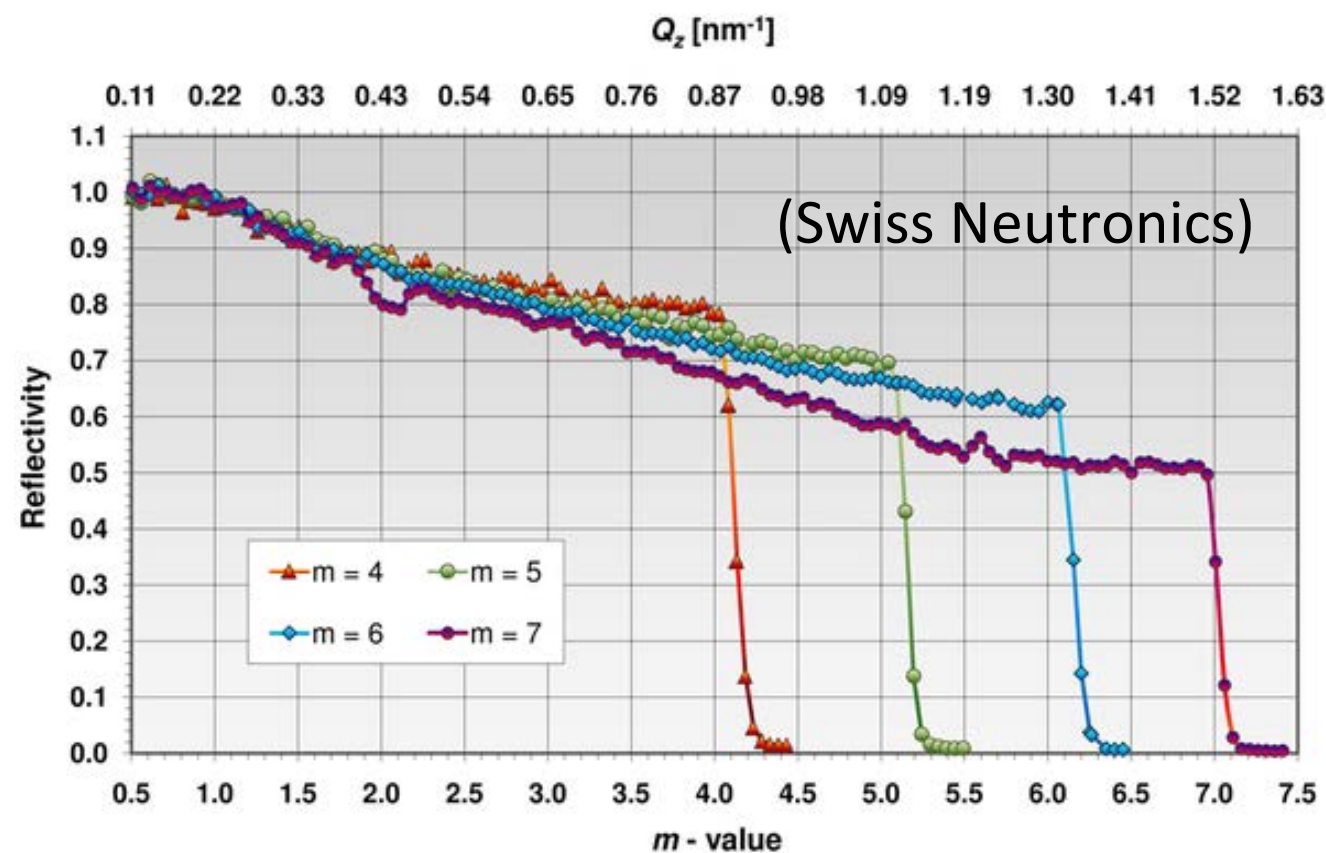

- High-m super-mirror
- Residual B field  $< 5$  nT
- Good vacuum  $< 10^{-5}$  Pa

MC optimization of parameters ongoing!

# Supermirror Reflector

- Crucial in acceptance gain
  - 2D, so acceptance scales quadratically
  - Modern multi-layer supermirrors have good reflectivity at increasingly large momentum transfers

Active R&D at  
Nagoya University,  
with devices used  
at JPARC

Ni reflectivity  $\rightarrow 0$  defines  $m=1$

# Detector

- Anti-neutron annihilation target
  - High annihilation probability, low Z, high transparency to neutrons
    - ILL experiment used a carbon foil, 130  $\mu\text{m}$  thick
- Annihilation produces pions,  $\langle n \rangle \sim 5$
- Background suppression:
  - Precise annihilation vertex identification of multitrack events
  - Good mass and position resolution
  - Beam time structure? (Mainly for background control samples)

# Detector

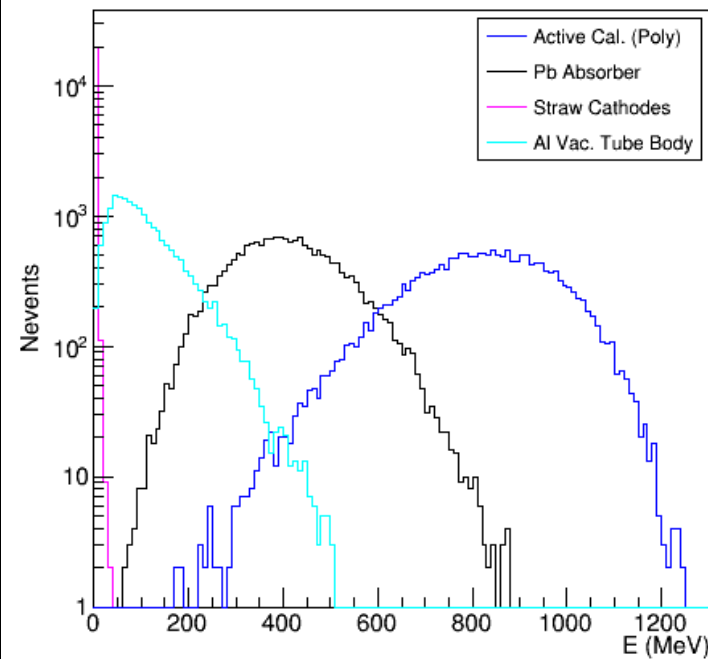

# Early Simulations: Detector

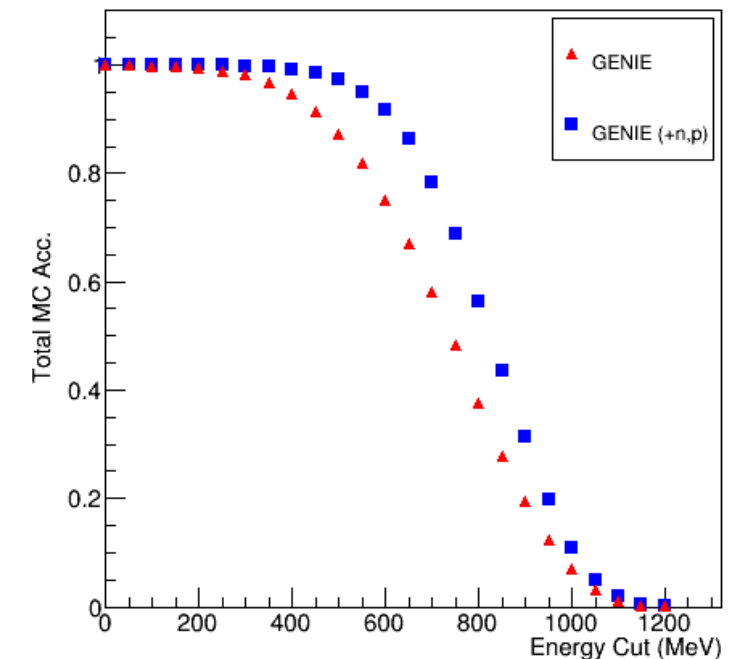

G4-based

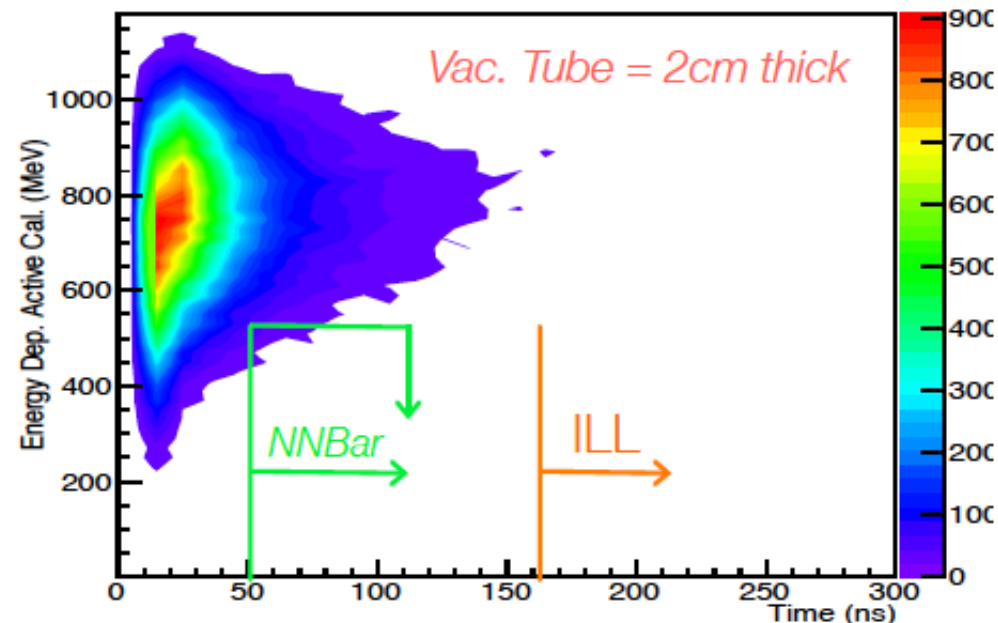

Energy Dep. in Detector Bodies

MC Acc. vs. Active Cal. Energy Cut (signal)

Edep Active Cal. vs. Time (Towers  $\geq 2$ )

Edep Active Cal. vs. Time (Towers  $\geq 2$ )

Identify Target  
Improvements over ILL

acceptance  
~90% (x1.8)

X3 red. in timing  
window (50 ns)

Lots of possibilities for detector development!

# Expected Sensitivity

# Potential Gains wrt ILL

Brightness		$\geq 1$
Moderator Area	Needs large aperture	2
Angular Acceptance	2D, so quadratic sensitivity	40
Length	Scale with $t^2$ , so $L^2$	5
Run Time	ILL run was 1 year	3
Total		$\geq 1000$

x 1000 in probability, reach  $\tau \sim 2\text{-}3 \times 10^9 \text{ s}$

# Early Simulations: Sensitivity

- Neutron spectrum files from ESS
- 50% detection efficiency (as for ILL)

# Collaboration

## Expression of Interest for A New Search for Neutron-Anti-Neutron Oscillations at ESS

	Name	Affiliation
<b>Main proposer</b>	Gustaaf Brooijmans	Columbia University
<b>Co-proposers</b>	Torsten Åkesson	Lund University
	David Baxter	Indiana University
	Hans Calen	Uppsala University
	Lorenzo Calibbi	Université Libre de Bruxelles
	Luis Castellanos	University of Tennessee
	Joakim Cederkäll	Lund University
	Peter Christiansen	Lund University
	Christophe Clément	Stockholm University

	Oxana Smirnova	Lund University
	Per Erik Tegner	Stockholm University
	Camille Theroine	ESS
	Lawrence Townsend	University of Tennessee
	Rick Van Kooten	Indiana University
	Albert Young	North Carolina State University
<b>ESS coordinator</b>	Camille Theroine	ESS

- Collaboration growing
  - ESS very supportive
    - Agreed to target area modifications needed
  - Revisiting sensitivity studies now that ESS has frozen moderator configuration
- Regular collaboration meetings

Ongoing work modeling aspects of the oscillation coherence, magnetic field sensitivity, and detailed models of the ESS target and moderator geometry

# Conclusion

- Search for  $n$ - $\bar{n}$  oscillation strongly motivated:
  - $\Delta B=2$  baryon number violation appears in many models
  - Probe scales from  $10^5$  -  $10^{12}$  GeV
  - Connection with baryogenesis, neutrino masses, ...
- Experiment well within current capabilities
  - Very low technical risk – plenty of opportunities to optimize the approach and improve the project!
- Substantial community exists
  - Bridges particle and nuclear physics communities
  - Synergies with ESS neutron scattering community
- Complementary to planned science at LHC (observable particle production...) and the Underground Physics program
- Exploration of test beam program and  $n$ - $n'$  measurements by collaboration is underway
- Opportunities to gain a factor 1000 in sensitivity to processes at core of our existence and understanding of universe are rare

Should not be squandered
