## Interaction of Low Energy (0-20 eV) Electrons with Sulfur Dioxide on Ice Surfaces

*Tuesday, January 9, 2018 12:35 PM (1h 30m)*

We studied the interaction of low energy (0-20 eV) electrons with sulfur dioxide (SO<sub>2</sub>) on a crystalline ice film surface. An ice film was prepared by H<sub>2</sub>O vapor deposition on a Pt(111) substrate at 150 K for thickness of >100 BL inside a vacuum chamber and was annealed at 165 K to produce a crystalline ice film with a flat (0001) surface. SO<sub>2</sub> gas was adsorbed on the crystalline ice film through a tube doser. The surface adsorbates were analyzed using the methods of Cs<sup>+</sup> reactive ion scattering (RIS) and low energy sputtering (LES), which revealed molecular SO<sub>2</sub> adsorption at ~95 K and the occurrence of the hydrolysis of SO<sub>2</sub> at >100 K.<sup>1</sup> We irradiated low energy electrons, produced from an electron flood gun, onto the ice film surface with adsorbed SO<sub>2</sub> at 95 K. While the low energy electrons transmit through an ice film, they were trapped quite efficiently by the SO<sub>2</sub> adsorbates on the surface. The amount of SO<sub>2</sub>-trapped electrons was estimated by measuring the film voltage with a Kelvin probe at various incident energies of the electrons. RIS and LES measurements of the surface show that the electron-trapping by SO<sub>2</sub> produces various negative ion species, such as OH<sup>-</sup>, SO<sub>2</sub><sup>-</sup>, SO<sub>3</sub><sup>-</sup>, and HSO<sub>3</sub><sup>-</sup>.

### Significance statement

SO<sub>2</sub> adsorbates on crystalline ice film can trap low energy (0-20 eV) electrons, and it produces various negative ion species such as OH<sup>-</sup>, SO<sub>2</sub><sup>-</sup>, SO<sub>3</sub><sup>-</sup>, and HSO<sub>3</sub><sup>-</sup> at 95 K.
