C. Smorra et al., EPJ-Special Topics, The BASE Experiment, (2015)

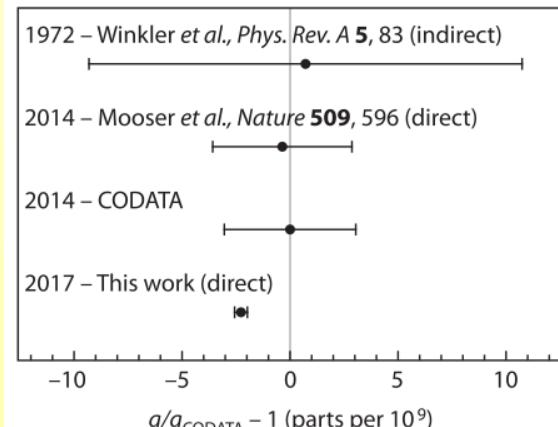

BASE achievements since 2011

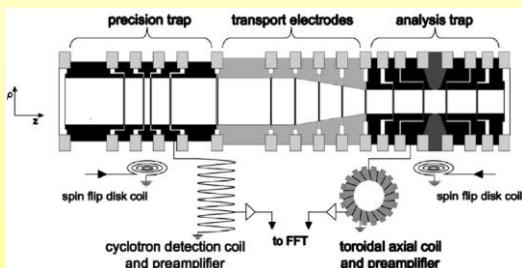

Observation of spin flips with a single trapped proton

Most precise proton g-factor measurement

Application of the double Penning-trap technique

A. Mooser, et al., PLB 723, 78 (2013)

$$g/2 = 2.792\,847\,350\,(9)$$

A. Mooser et al., Nature 509, 596 (2014).

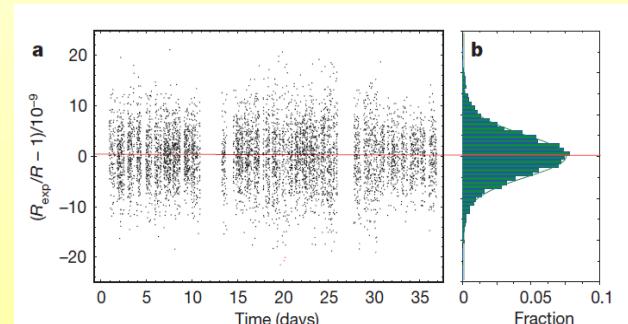

First direct high precision measurement of the proton magnetic moment.

$$g/2 = 2.792\,847\,344\,62\,(82)$$

G. Schneider et al., Science 358, 1081 (2017).

Precise CPT test with baryons

S. Ulmer, et al., Nature 524, 196 (2015)

$$1 + \frac{(q/m)_{\bar{p}}}{(q/m)_p} = 1(69) \times 10^{-12}$$

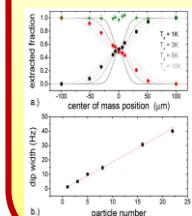

$$R_{\text{exp,c}} = 1.001\,089\,218\,755\,(64)\,(26)$$

To be improved by another factor of 10 to 100

Reservoir trap for antiprotons

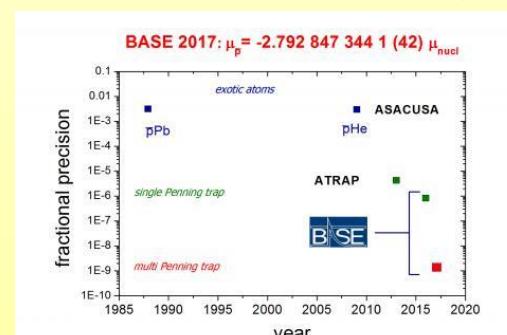

C. Smorra, et al., Int. Journ. Mass Spec. 389, 10 (2015).

Idea: Enable operation with antiprotons independent of accelerator run times.

Most precise antiproton g-factor measurement

H. Nagahama, et al., Nature Comms. 8, 14084 (2017)
C. Smorra et al., Nature 550, 371 (2017)

$$g/2 = 2.792\,846\,5\,(23)$$

Sixfold improvement compared to previous measurement

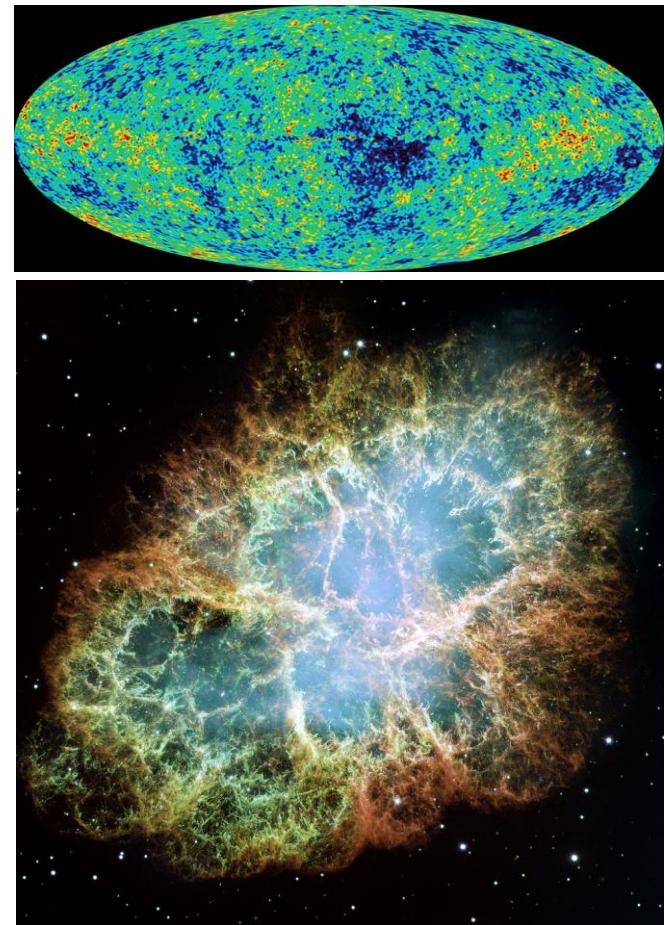

$$g/2 = 2.792\,847\,344\,1\,(42)$$

350-fold improvement compared to previous measurement

Problem: Big Bang Scenario and Consequences

1. A cosmic microwave background should exist as a fire-ball remnant of the Big Bang
 1. 1965 Penzias and Wilson **observed CMWB with a black body spectrum of 2.73(1)K, by far too intense to be of stellar origin.**
2. Understandable Big Bang nucleosynthesis scenario **describes exactly the observed light element abundances as found in «cold» stellar nebulae.**
3. Using the models which describe 1. and 2.:

Prediction		Observation	
Baryon/Photon Ratio	10^{-18}	Baryon/Photon Ratio	10^{-9}
Baryon/Antibaryon Ratio	1	Baryon/Antibaryon Ratio	0.0001

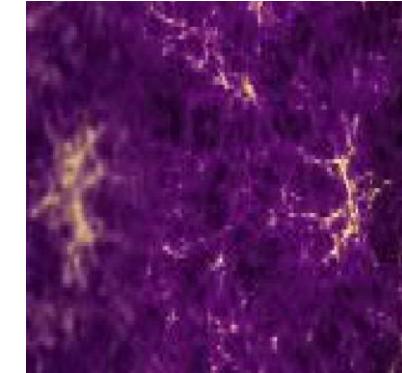

Following the current Standard Model of the Universe our predictions of baryon to photon ratio are **wrong by about 9 orders of magnitude**

WE HAVE A PROBLEM

mechanisms which created the obvious
baryon/antibaryon asymmetry in the universe
have yet to be understood

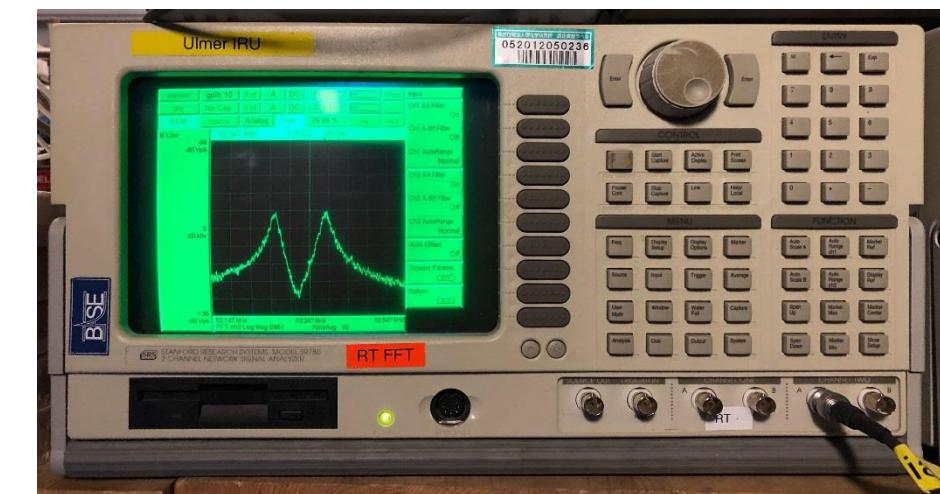

One strategy: Compare the fundamental
properties of matter / antimatter conjugates
with ultra high precision

A special place (in the universe?) – the BASE trap

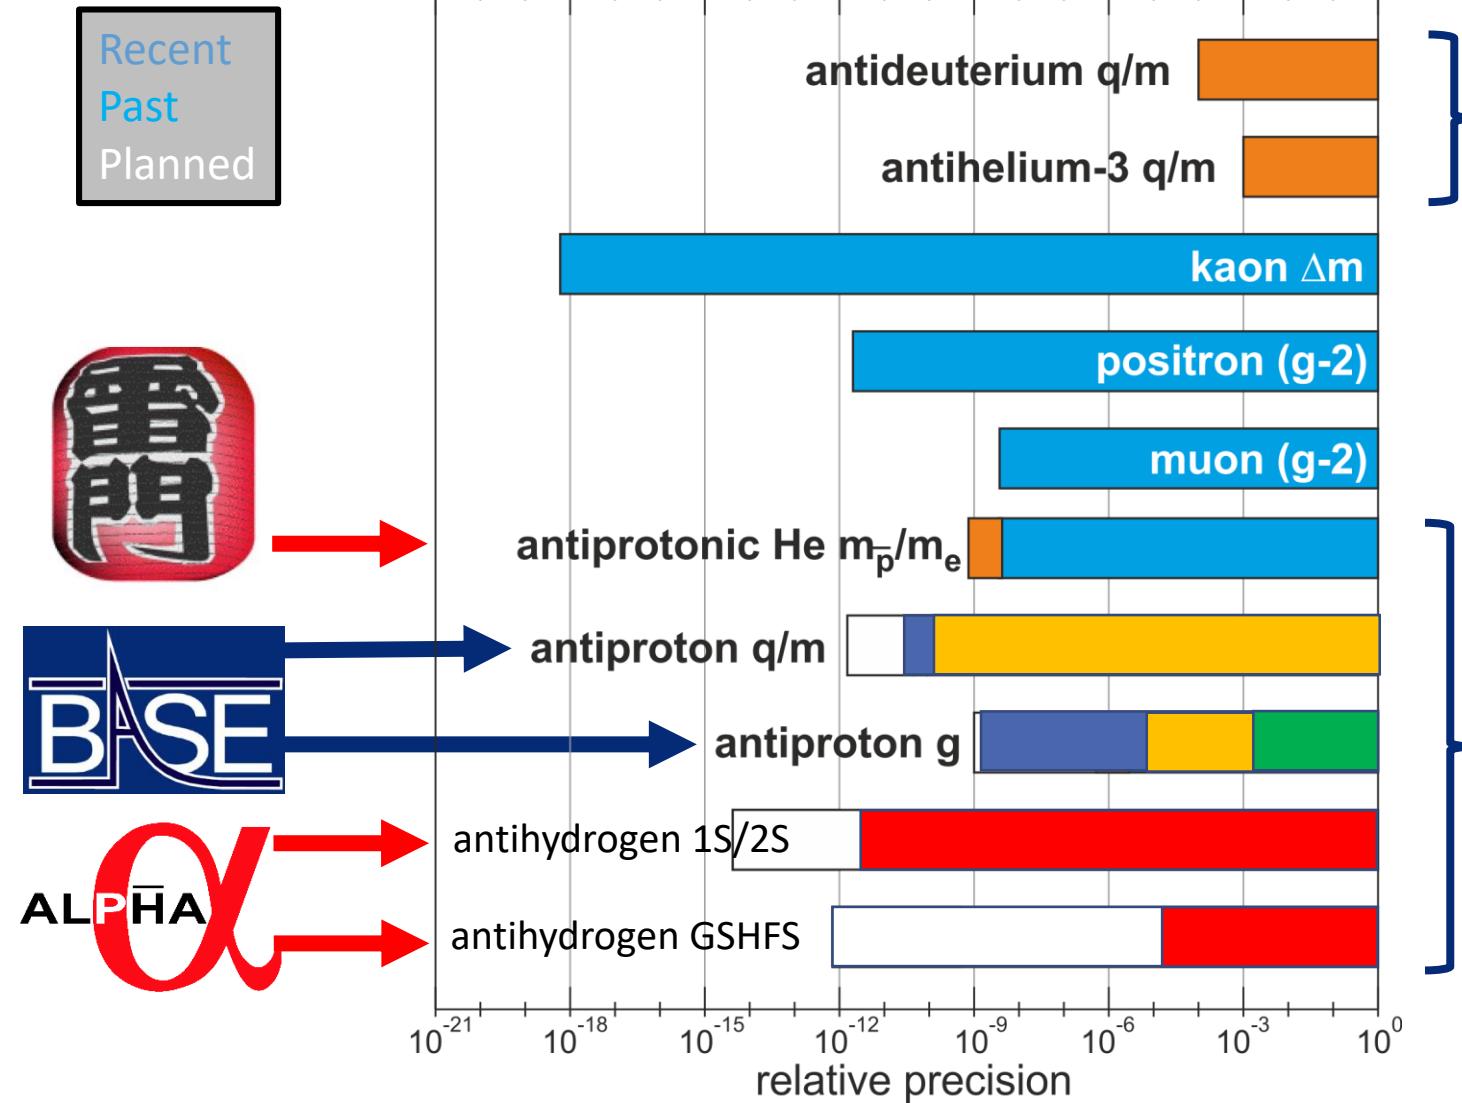

- We have
 - A vacuum of 5e-19 mbars
 - comparable to pressures in the interstellar medium
 - Antiproton storage times of several 10 years.
 - Not more than 3000 atoms in a vacuum volume of 0.5l
 - Order 100 to 1000 trapped antiprotons
 - A local inversion of the baryon asymmetry

BASE ANTIMATTER INVERSION	
local volume	0.0001 ³ m ³
Baryons in local trap volume	1.65*10 ⁻⁷
Antibaryon in local trap volume	100
Antibaryon/Baryon Ratio	5.9*10⁸
Ratio Inversion	3.8*10¹²

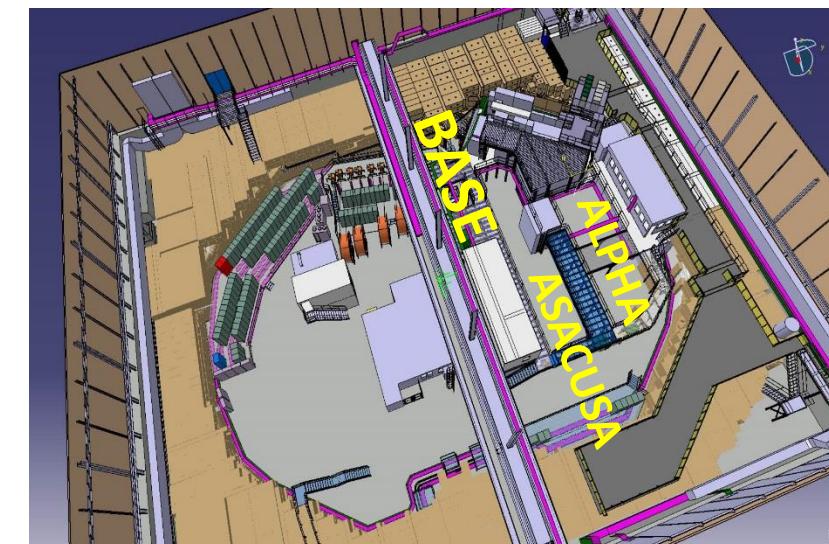

With this instrument: Investigate properties of antimatter very precisely

CPT tests based on particle/antiparticle comparisons

Limits on Exotic Physics – ONE example

- Test the Standard Model (CPT invariance) by comparing the fundamental properties of protons and antiprotons with high precision

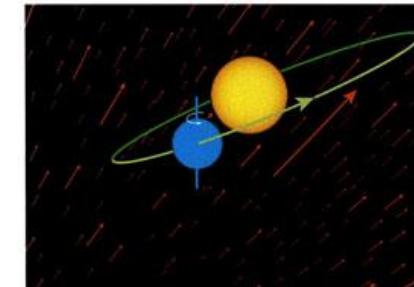

$$H \psi = (H_0 + V_{exotic}) \psi$$

$$\Delta E_{exotic} = \langle \psi | V_{exotic} | \psi \rangle$$

$$(i\gamma^\mu D_\mu - m - [a_\mu \gamma^\mu - b_\mu \gamma_5 \gamma^\mu]) \psi = 0$$

Dirac equation

CPT-odd modifications

$$b_\mu \gamma_5 \gamma^\mu \rightarrow b_x \begin{pmatrix} -\sigma_x & 0 \\ 0 & \sigma_x \end{pmatrix} + b_y \begin{pmatrix} -\sigma_y & 0 \\ 0 & \sigma_y \end{pmatrix} + b_z \begin{pmatrix} -\sigma_z & 0 \\ 0 & \sigma_z \end{pmatrix}$$

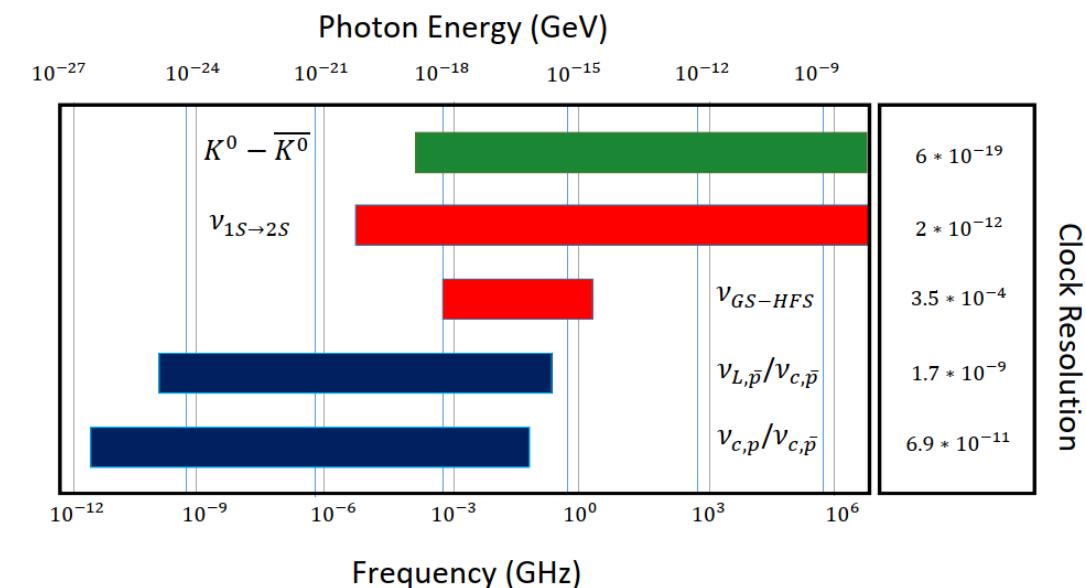

Pseudo-magnetic field, with different coupling to matter and antimatter, respectively

$$\Delta V_{int} = \tilde{b}_{z,D} \begin{pmatrix} 0 & 0 \\ 0 & \pm \sigma_z \end{pmatrix}$$

V. A. Kostelecky, N. Russell,
0801.0287v10 (2017).

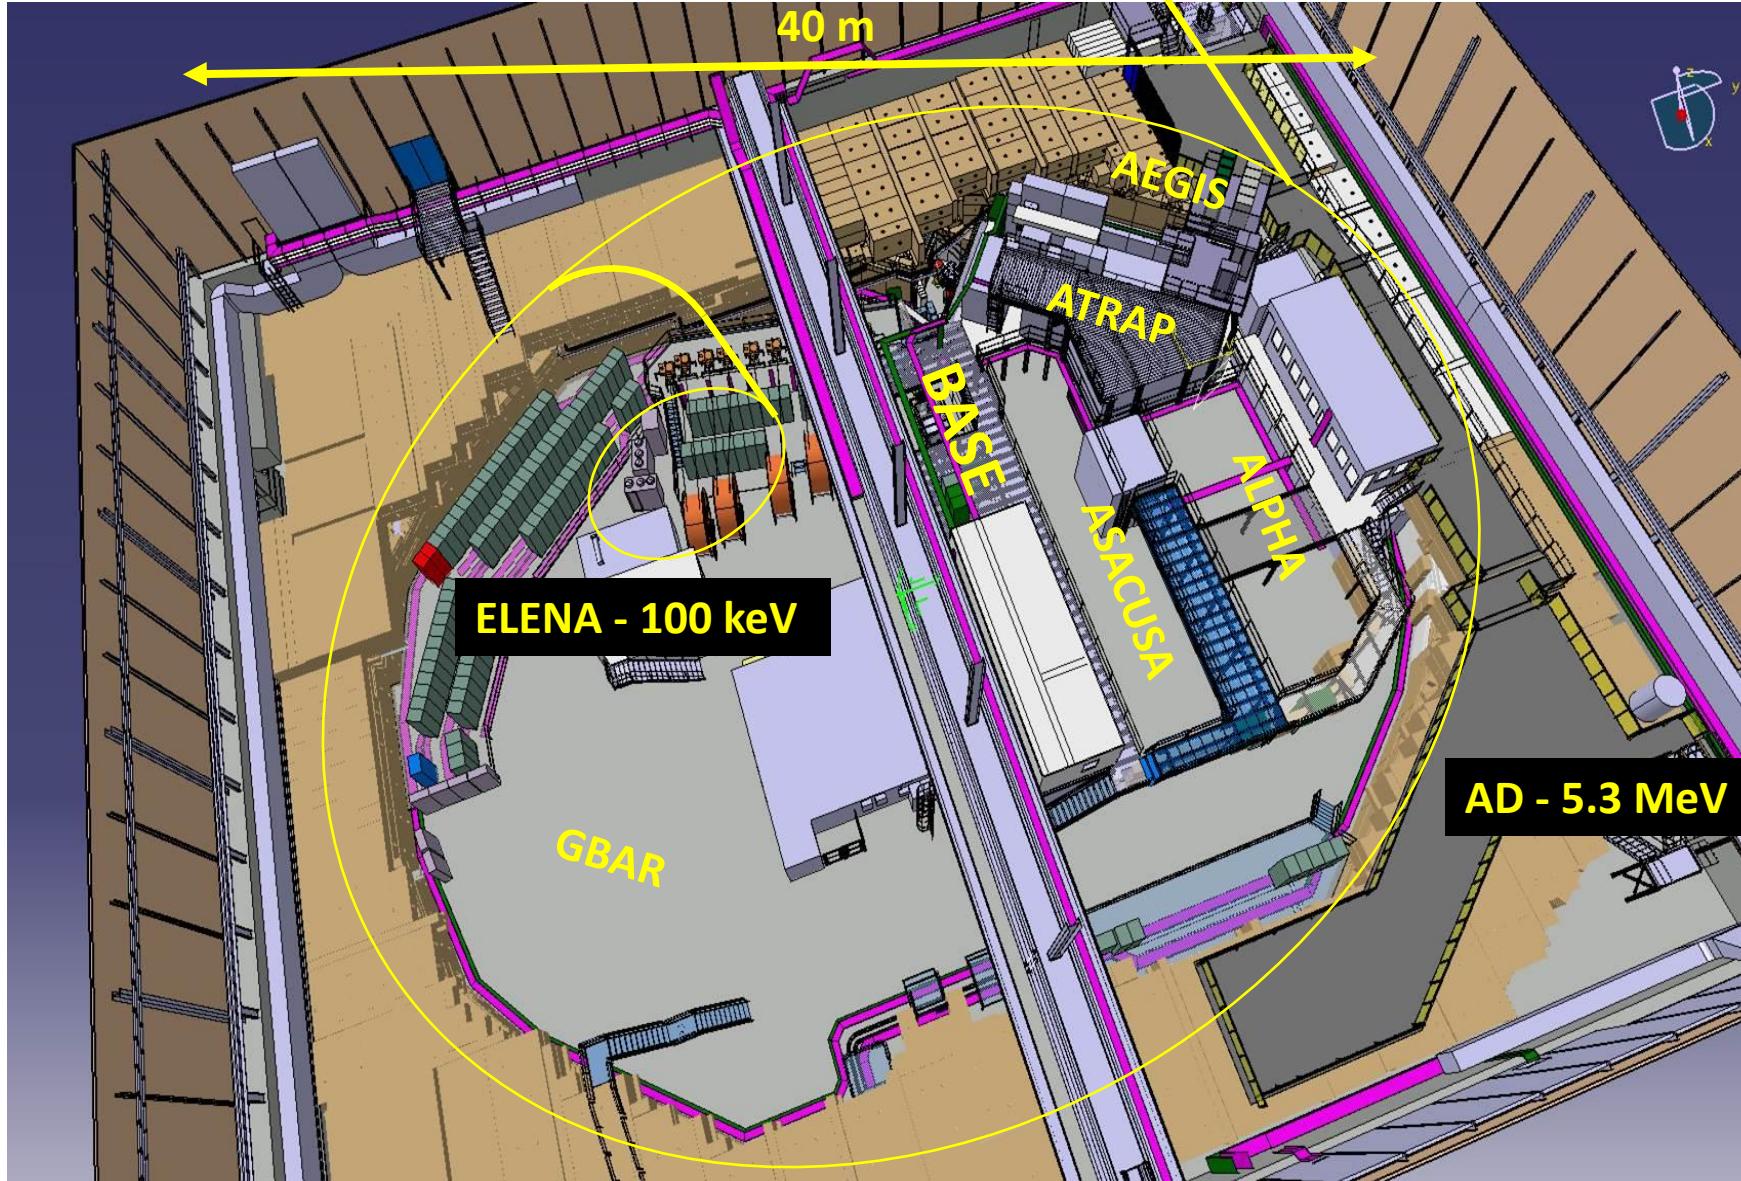

Would correspond to the discovery of a boson field which exclusively couples to antimatter.

Particles not continuously available

Trap for efficient cyclotron cooling

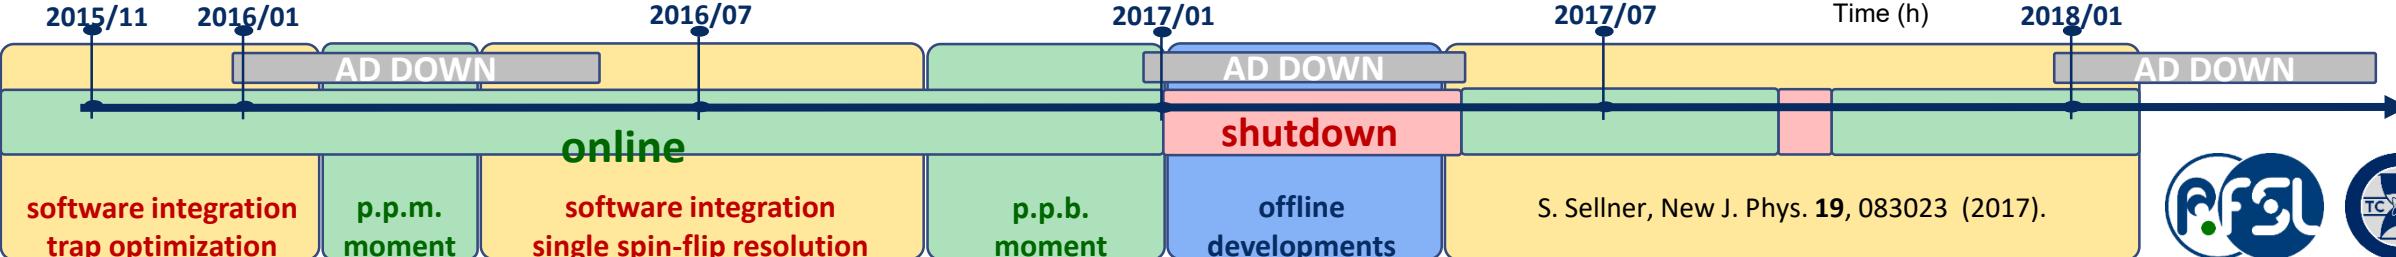

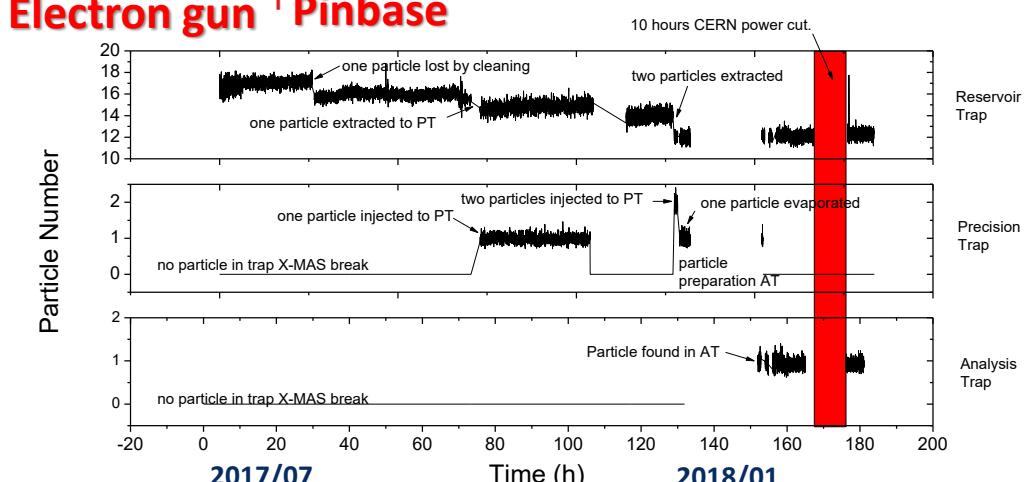

S. Ulmer et al., BASE TDR, CDS (2013).

Reservoir Trap: Stores a cloud of antiprotons, suspends single antiprotons for measurements. Trap is “power failure save”.

Precision Trap: Homogeneous field for frequency measurements, $B_2 < 0.5 \mu\text{T} / \text{mm}^2$ (**10 x improved**)

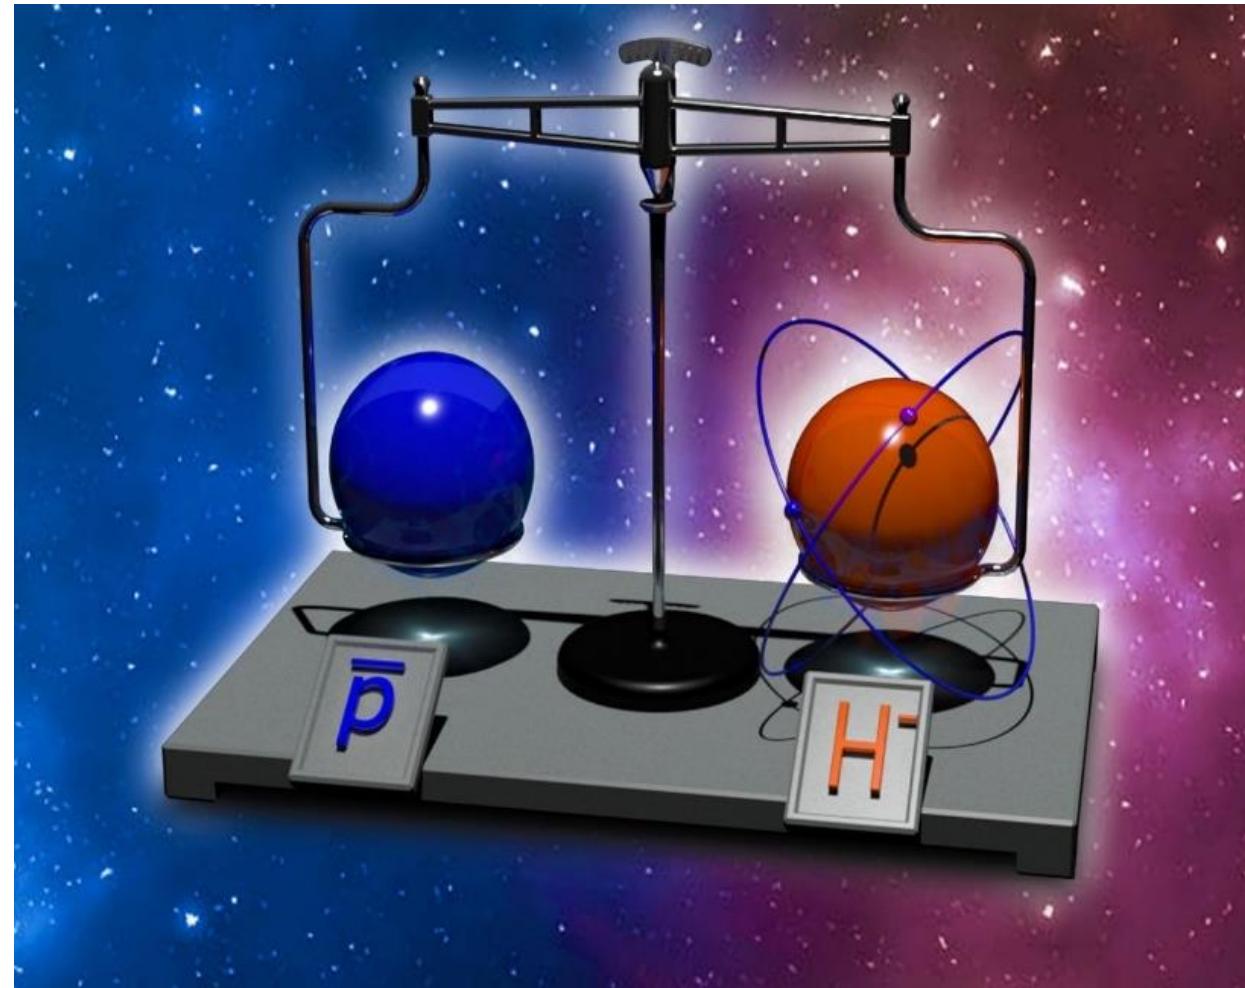

Cooling Trap: Fast cooling of the cyclotron motion, $1/\gamma < 4 \text{ s}$ (**10 x improved**)

Analysis Trap: Inhomogeneous field for the detection of antiproton spin flips, $B_2 = 300 \text{ mT} / \text{mm}^2$

S. Sellner, New J. Phys. 19, 083023 (2017).

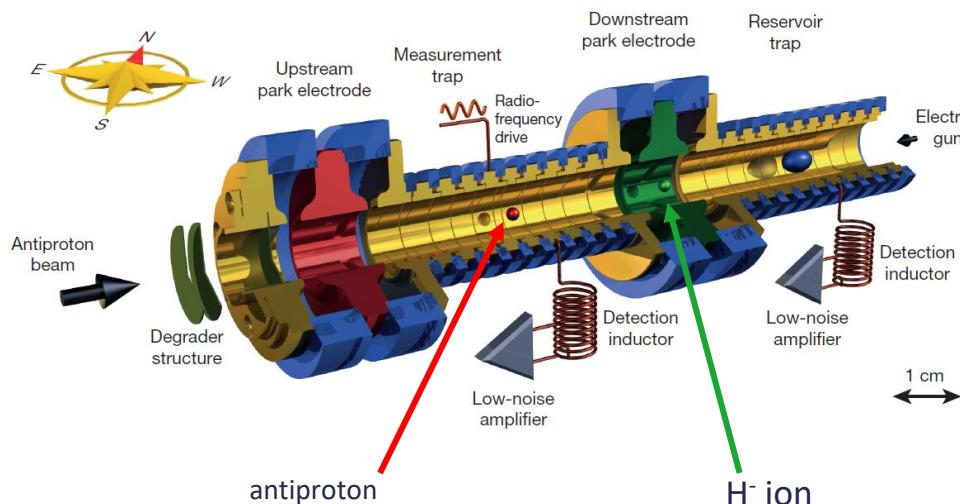

Proton/Antiproton Charge-to-Mass Comparison

S. Ulmer, et al., Nature **524**, 196 (2015)

Measurement configuration

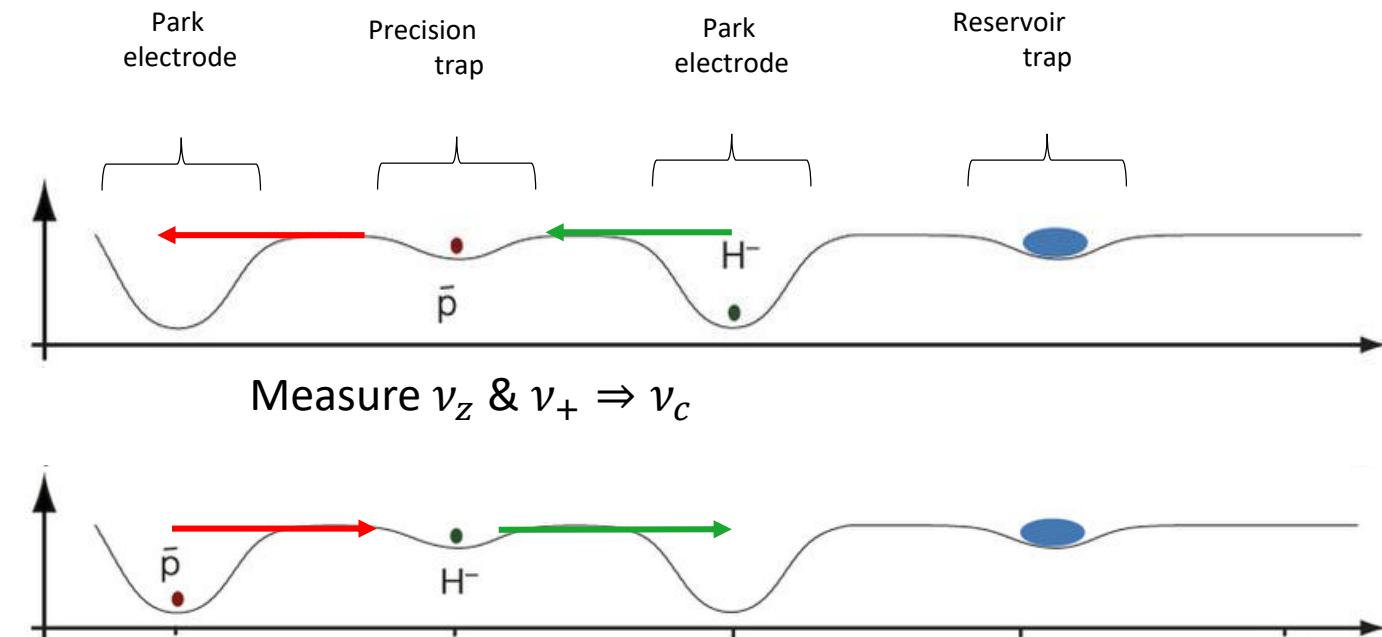

Extract antiprotons and H⁻ ions, compare cyclotron frequencies

$$R = \frac{v_{c,\bar{p}}}{v_{c,H^-}} = \frac{(q/m)_{\bar{p}}}{(q/m)_{H^-}} \times \frac{B/2\pi}{B/2\pi} = \frac{(q/m)_{\bar{p}}}{(q/m)_{H^-}}$$

$$m_{H^-} = m_p \left(1 + 2 \frac{m_e}{m_p} - \frac{E_b}{m_p} - \frac{E_a}{m_p} + \frac{\alpha_{\text{pol},H^-} B_0^2}{m_p} \right)$$

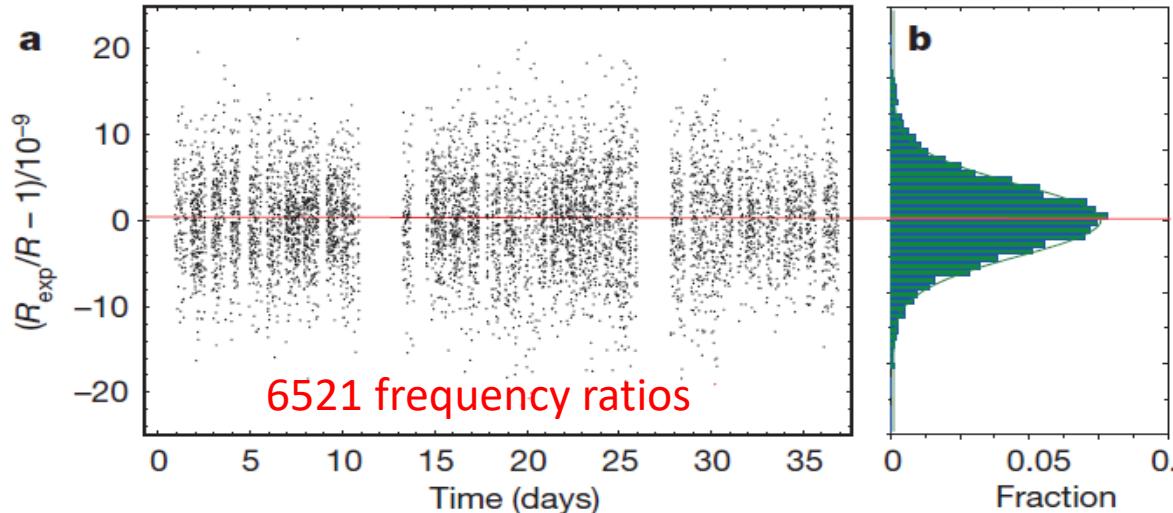

$$R_{\text{theo}} = 1.001\ 089\ 218\ 754\ 2(2)$$

Comparison of H-/antiproton cyclotron frequencies:
One frequency ratio per 4 minutes with ~ 6 ppb uncertainty

inspired by G. Gabriesle et al., PRL 82, 3199 (1999).

Proton to Antiproton Q/M: Physics

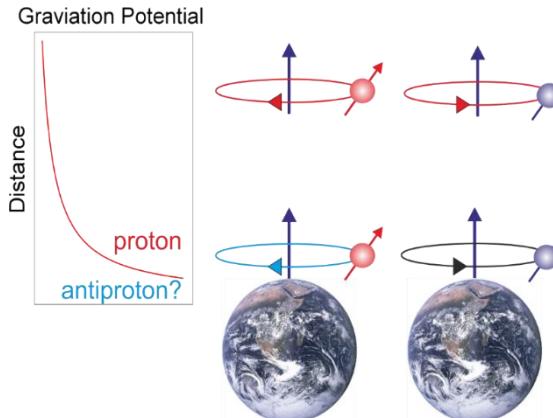

$$\frac{(q/m)_{\bar{p}}}{(q/m)_p} + 1 = 1(69) \times 10^{-12}$$

- In agreement with CPT conservation
- Exceeds the energy resolution of previous result by a factor of 4.

S. Ulmer, et al., Nature 524, 196 (2015)

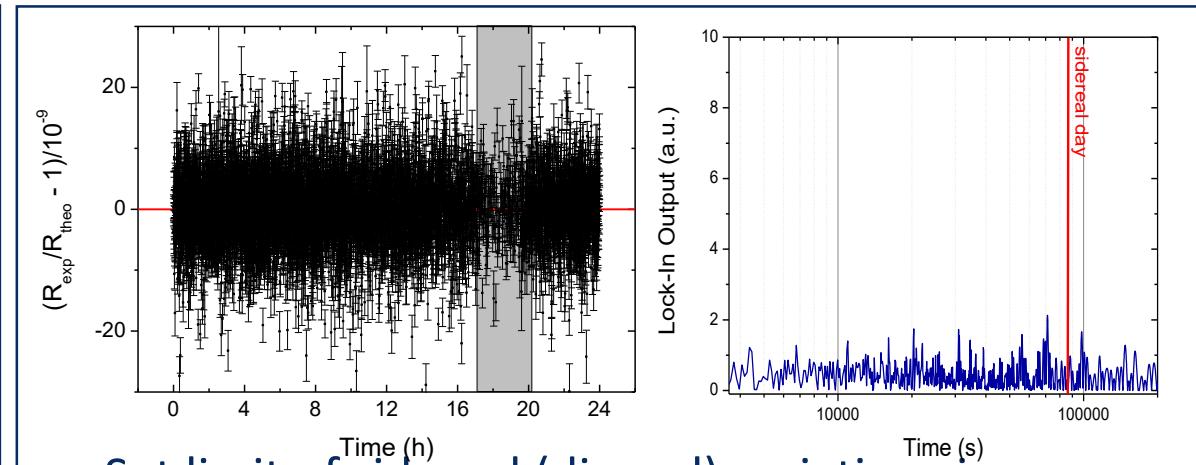

- Constrain of the gravitational anomaly for antiprotons:

Our 69 ppt result sets a new upper limit of

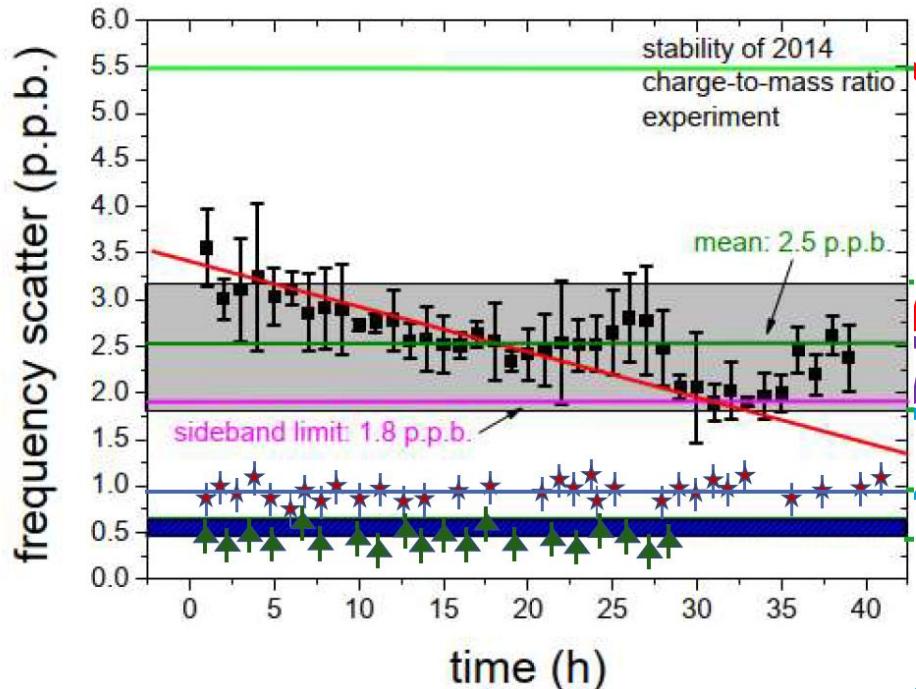

$$|\alpha_g - 1| < 8.7 \times 10^{-7}$$

- Conclusion:
Matter and Antimatter clocks run at the same frequency

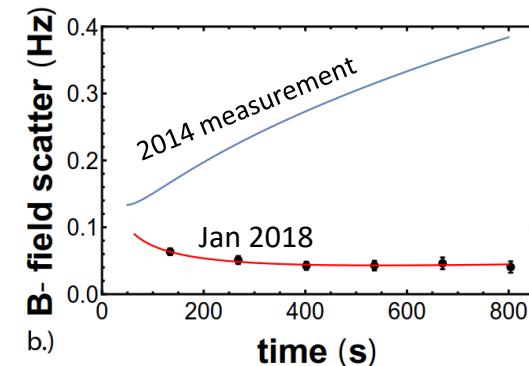

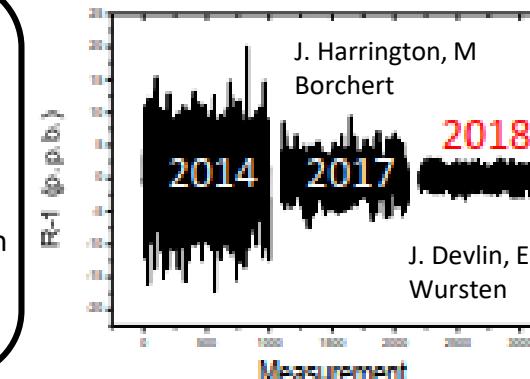

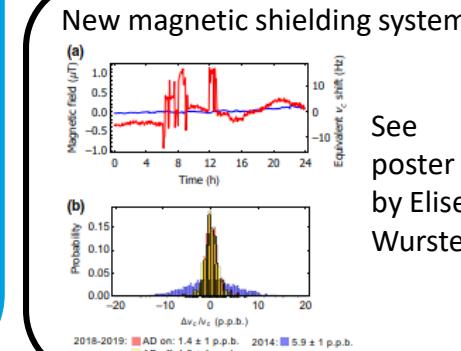

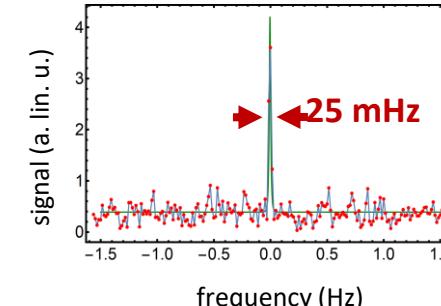

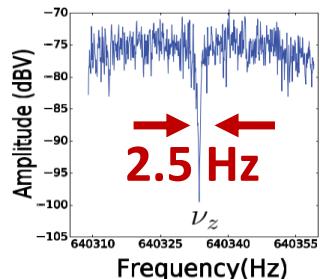

- Set limit of sidereal (diurnal) variations in proton/antiproton charge-to-mass ratios to < 0.72 ppb/day

Progress towards a better q/m measurement

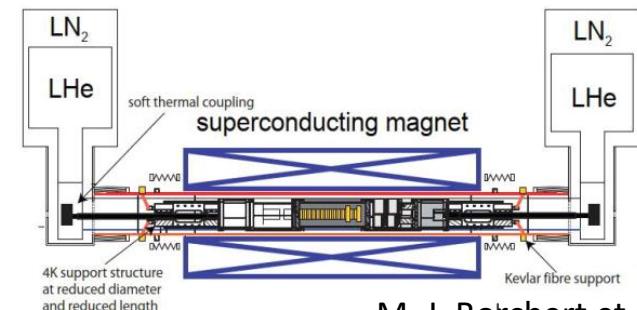

peak measurement technique

Better stabilisation of cryoliquid pressure, temperature improves magnetic stability

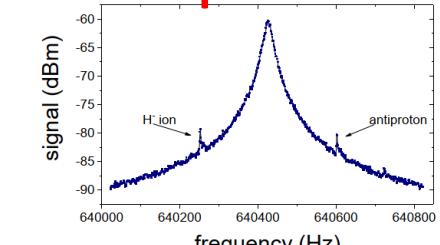

J. A. B.-Harrington et al.

Mechanical upgrade more stable and lower heat load means fewer vibrations

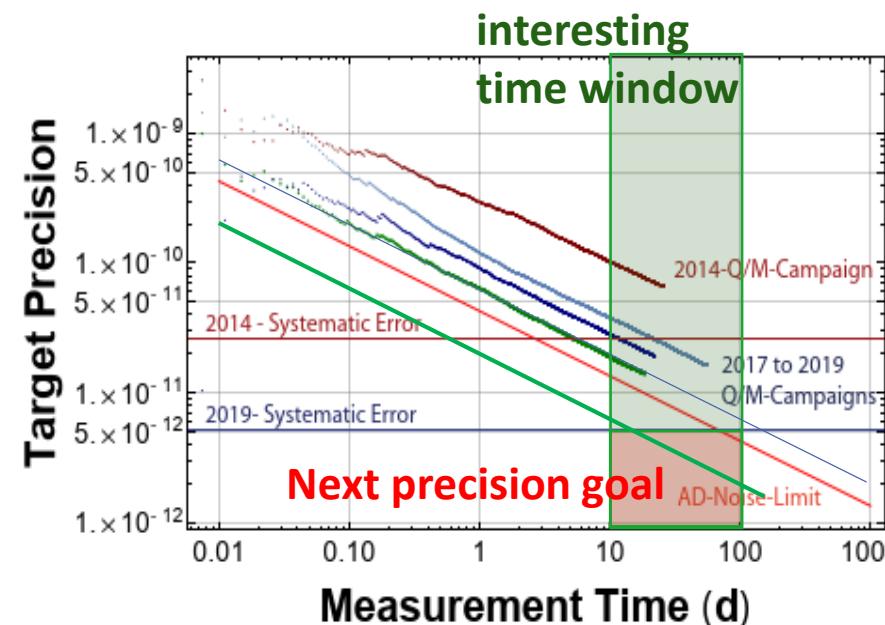

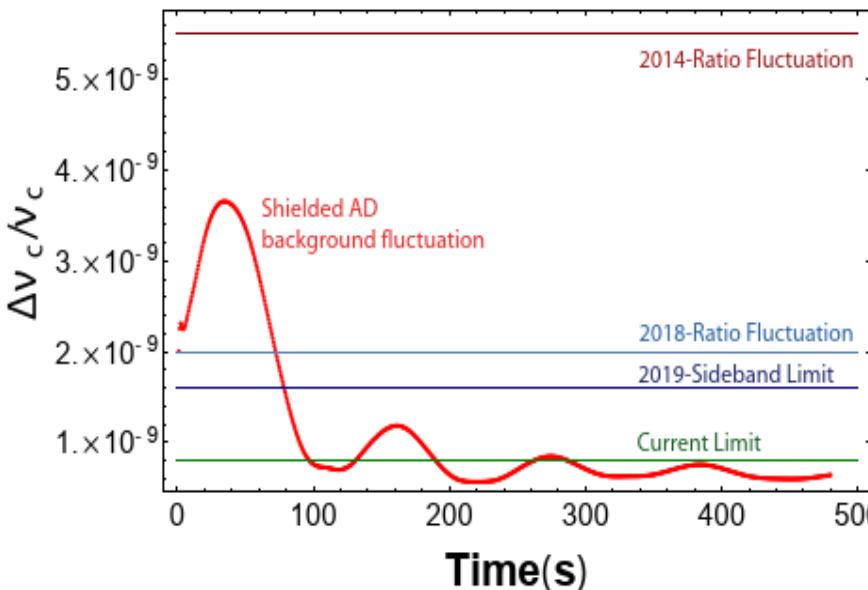

M. J. Borchert et al.

Next step:

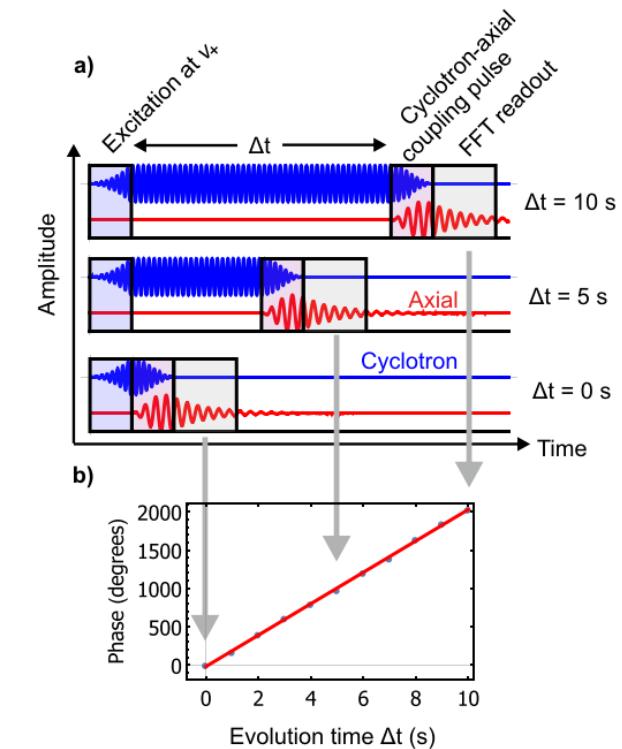

Future Perspective

- Reached a ratio uncertainty of order 10 p.p.t. to 20 p.p.t.
- What would be the next step?

Phase measurements indicate
300 p.p.t. scatter (120s cycle)

- In the AD hall with accelerator active we would not be able to significantly improve the ratio
- Started project to transport antiprotons out of the AD hall (ERC-grant Christian Smorra / BASE-STEP)

BASE

Experiment of the moment

The BASE collaboration at CERN has measured the antiproton magnetic moment with extraordinary precision, offering more than 100-fold improved limits on certain tests of charge-parity-time symmetry.

The BASE setup at CERN's Antiproton Decelerator.

The enigma of why the universe contains more matter than antimatter has been with us for more than half a century. While charge-parity (CP) violation can, in principle, account for the existence of such an imbalance, the observed matter excess is about nine orders of magnitude larger than what is expected from known CP-violating sources within the Standard Model (SM). This striking discrepancy inspires searches for additional mechanisms for the universe's baryon asymmetry, among which are experiments that test fundamental charge-parity-time (CPT) invariance by comparing matter and antimatter with great precision. Any measured difference between the two would constitute a dramatic sign of new physics. Moreover, experiments with antimatter systems provide unique tests of hypothetical processes beyond the SM that cannot be uncovered with ordinary matter systems.

The Baryon Antibaryon Symmetry Experiment (BASE) at CERN, in addition to several other collaborations at the Antiproton Decelerator (AD), probes the universe through exclusive antimatter "microscopes" with ever higher resolution. In 2017, following many years of effort at CERN and the University of Mainz in Germany, the BASE team measured the magnetic moment of the antiproton with a precision 350 times better than by any other experiment before, reaching a relative precision of 1.5 parts per billion (figure 1). The result followed the development of a multi-Penning-trap system and a novel

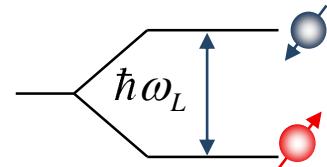

non-destructive physics. The BASE result relies on a quantum measurement scheme to observe spin transitions of a single antiproton in a non-destructive manner. In experimental physics, non-destructive observations of quantum effects are usually accompanied by a tremendous increase in measurement precision. For example, the non-destructive observation of electronic transitions in atoms or ions led to the development of optical frequency standards that achieve fractional precisions on the 10^{-15} level. Another example, allowing one of the most precise tests of CPT invariance to date, is the comparison of the electron and positron g-factors. Based on quantum nondemolition detection of the spin state, such studies during the 1980s reached a fractional accuracy on the parts-per-trillion level.

The latest BASE measurement follows the same scheme but targets the magnetic moment of protons and antiprotons instead of electrons and positrons. This opens tests of CPT in a totally different particle system, which could behave entirely differently. In practice, however, the transfer of quantum measurement methods from the electron/positron to the proton/antiproton system constitutes a considerable challenge owing to the

CERN COURIER, 3 / 2018.

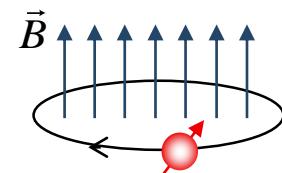

difficult

Continuous Stern Gerlach Effect

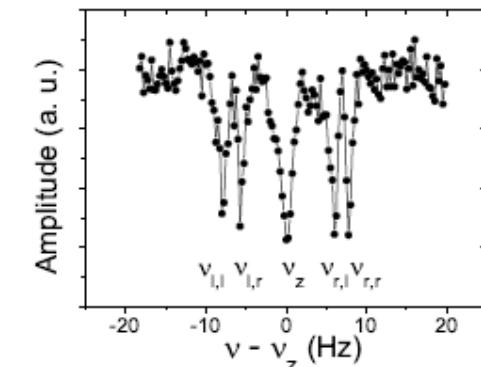

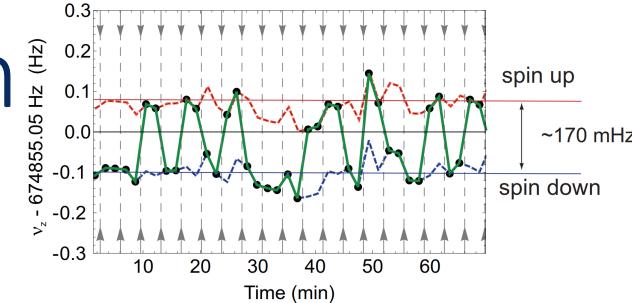

$$\frac{\mu_{\bar{p}}}{\mu_N} = \frac{g_{\bar{p}} e_{\bar{p}} / m_{\bar{p}}}{2 e_p / m_p} = \frac{v_L}{v_c}$$

straight forward

Image Current Measurements

C. Smorra *et al.*, Phys. Lett. B 769, 1 (2017)

S. Ulmer *et al.*, PRL 107, 103002 (2011)

Larmor Frequency – extremely hard

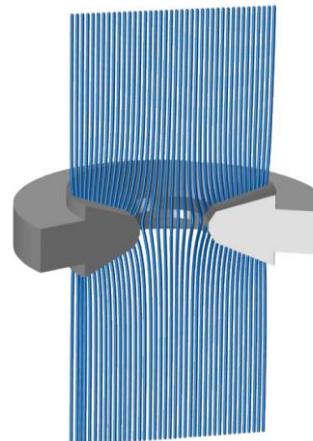

Measurement based on **continuous Stern Gerlach effect**.

Energy of magnetic dipole in magnetic field

$$\Phi_M = -(\vec{\mu}_p \cdot \vec{B})$$

Leading order magnetic field correction

$$B_z = B_0 + B_2 \left(z^2 - \frac{\rho^2}{2} \right)$$

This term adds a spin dependent quadratic axial potential
-> Axial frequency becomes a function of the spin state

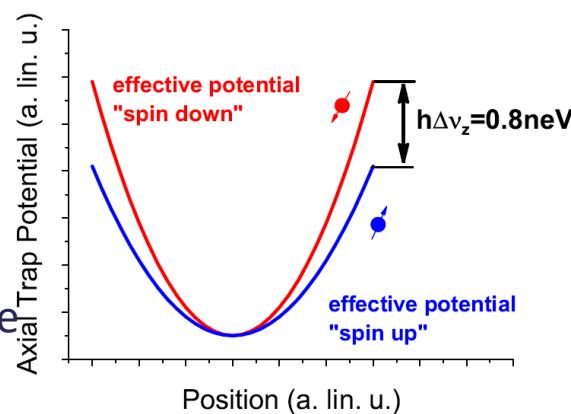

$$\Delta v_z \sim \frac{\mu_p B_2}{m_p v_z} := \alpha_p \frac{B_2}{v_z}$$

- Very difficult for the proton/antiproton system.

$$B_2 \sim 300000 \text{ T/m}^2$$

- Most extreme magnetic conditions ever applied to single particle.

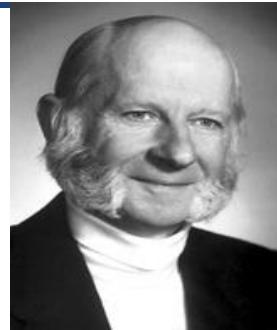

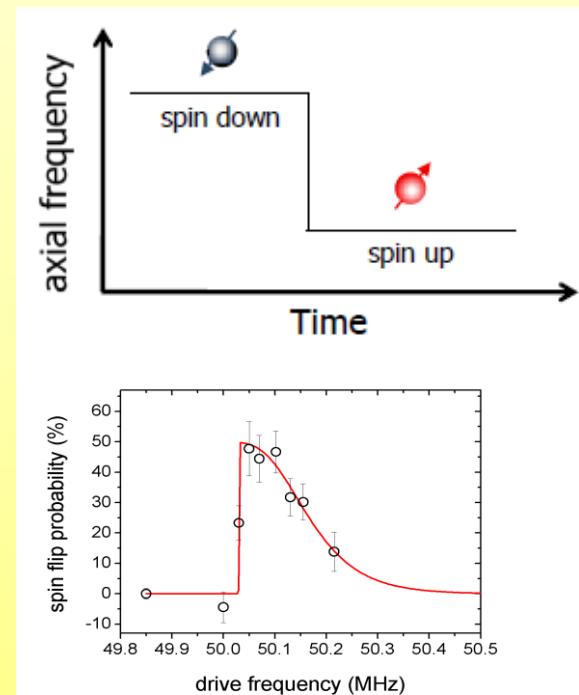

$$\Delta v_z \sim 170 \text{ mHz}$$

Single Penning trap method is limited to the p.p.m. level

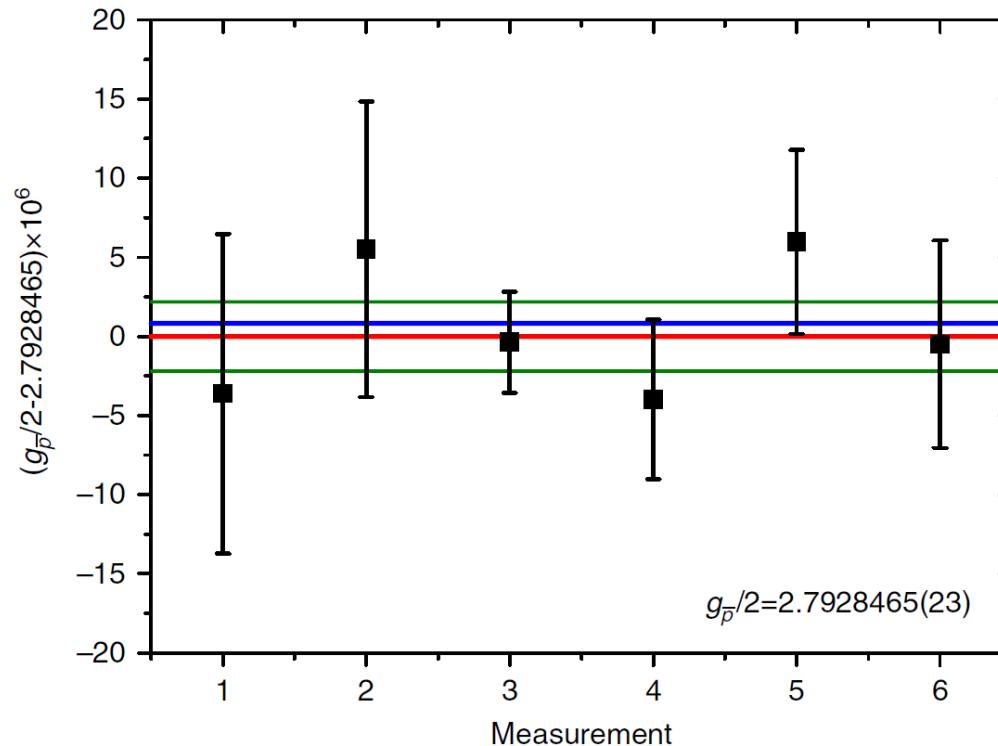

Frequency Measurement

Spin is detected and analyzed via an axial frequency measurement

Antiproton g-factor results – single trap

Performed 6 Larmor resonance and 12 cyclotron resonance scans

$$g_{\bar{p}}/2 = 2.7928465(23)$$

Six fold improved uncertainty of the antiproton magnetic moment

Table 1 | List of all SME-coefficients constrained by this measurement.

Coefficient	Constraint
$ \tilde{b}_p^Z $	$< 2.1 \times 10^{-22} \text{ GeV}$
$ \tilde{b}_p^{*Z} $	$< 2.6 \times 10^{-22} \text{ GeV}$
$ \tilde{b}_{F,p}^{XX} + \tilde{b}_{F,p}^{YY} $	$< 1.2 \times 10^{-6} \text{ GeV}^{-1}$
$ \tilde{b}_{F,p}^{ZZ} $	$< 8.8 \times 10^{-7} \text{ GeV}^{-1}$
$ \tilde{b}_{F,p}^{*XX} + \tilde{b}_{F,p}^{*YY} $	$< 8.3 \times 10^{-7} \text{ GeV}^{-1}$
$ \tilde{b}_{F,p}^{*ZZ} $	$< 3.0 \times 10^{-6} \text{ GeV}^{-1}$

Based on Ding, Y. & Kostelecký, V. A. *Lorentz-violating spinor electrodynamics and Penning traps*. *Phys. Rev. D* **94**, 056008 (2016).

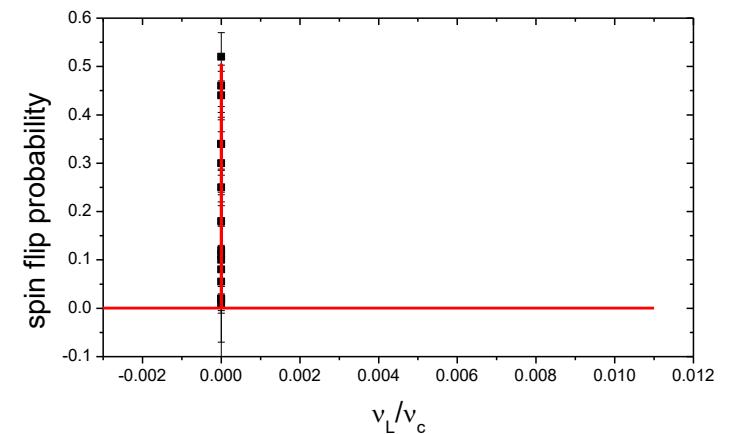

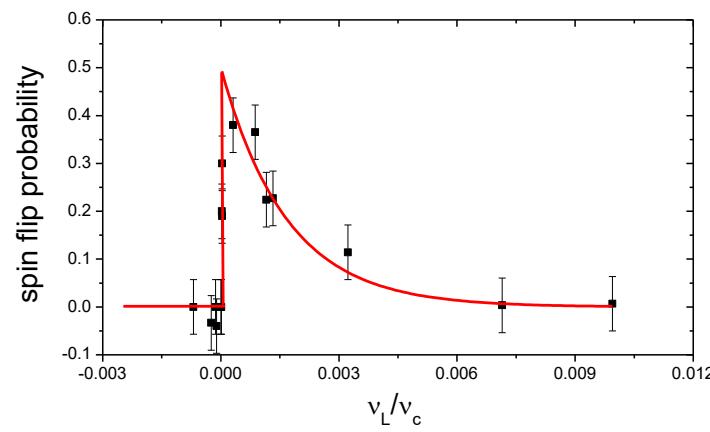

Respective limits on SME coefficients for CPT violation improved up to a factor 20

Earlier work: J. DiSciacca et al., *PRL* **110**, 130801 (2013).

H. Nagahama et al., *Nat. Comm.* **8**, 14084 (2017).

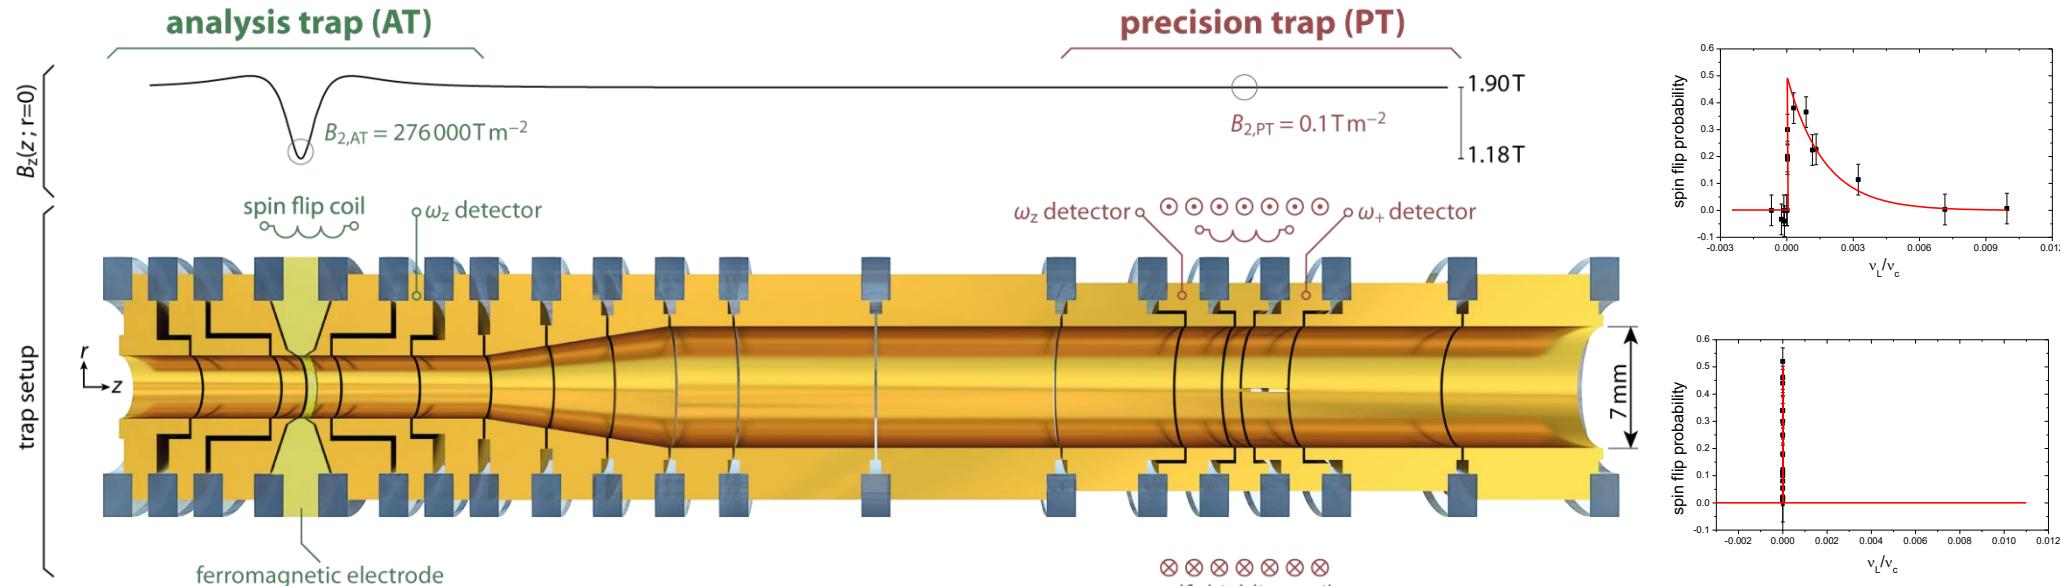

??? How can we do better ???

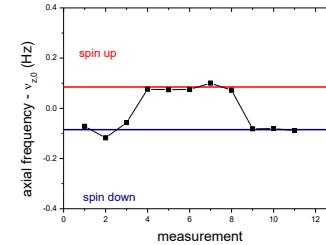

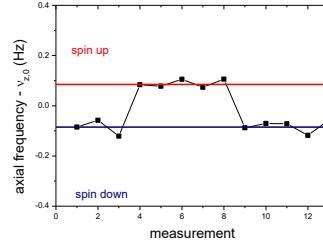

Next Step: The Double Penning-Trap Method

Invented at
Univ. of Mainz
by H. Haeffner,
W. Quint, G.
Werth and
company
(2000 - 2008)

Initialize the spin state

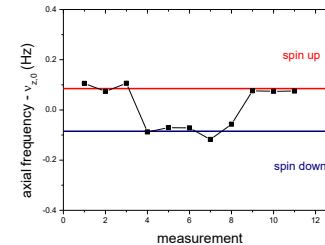

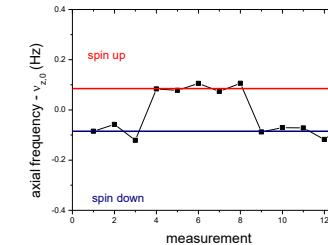

analyze the spin state

no spin-flip in PT

particle transport

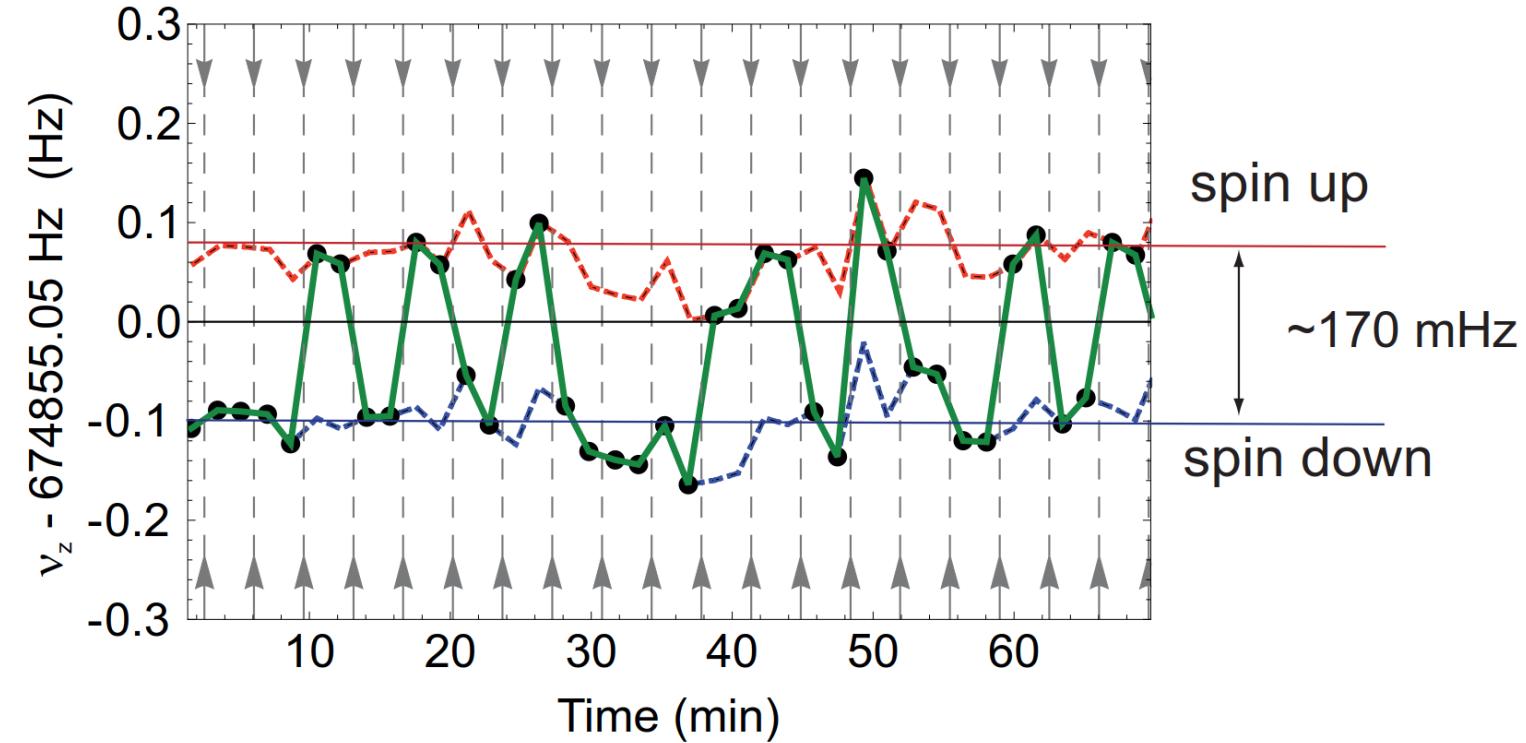

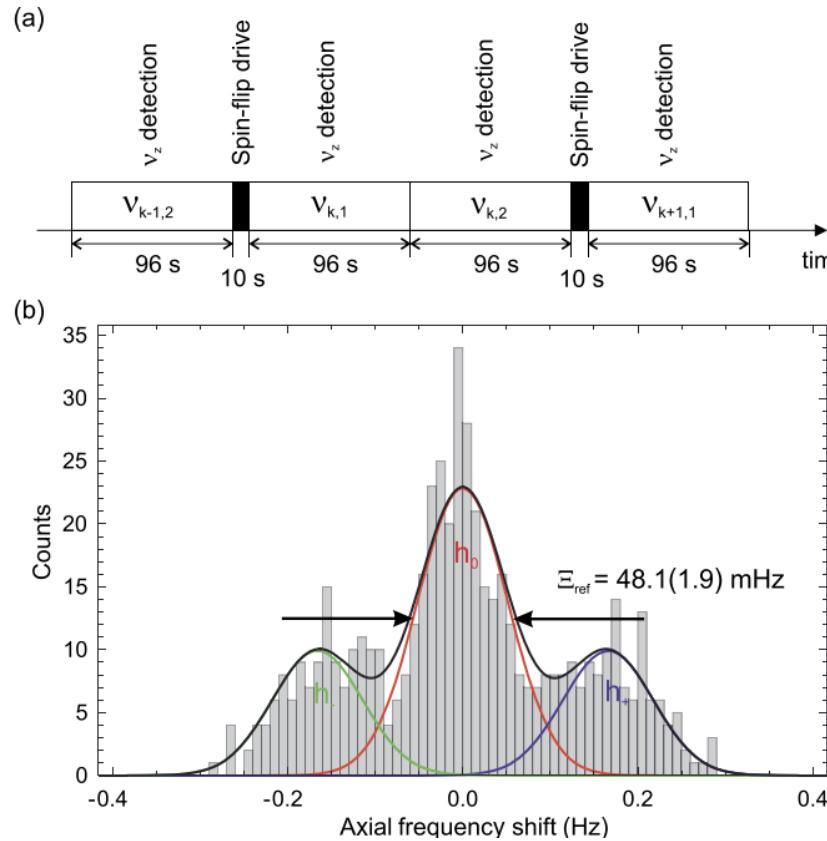

- 1.) measure cyclotron v_c
- 2.) drive spin transition at ν_{rf}

spin flipped in PT

measures spin flip probability as a function of the drive frequency in the homogeneous magnetic field of the precision trap

The holy-grail: single antiproton spin flips

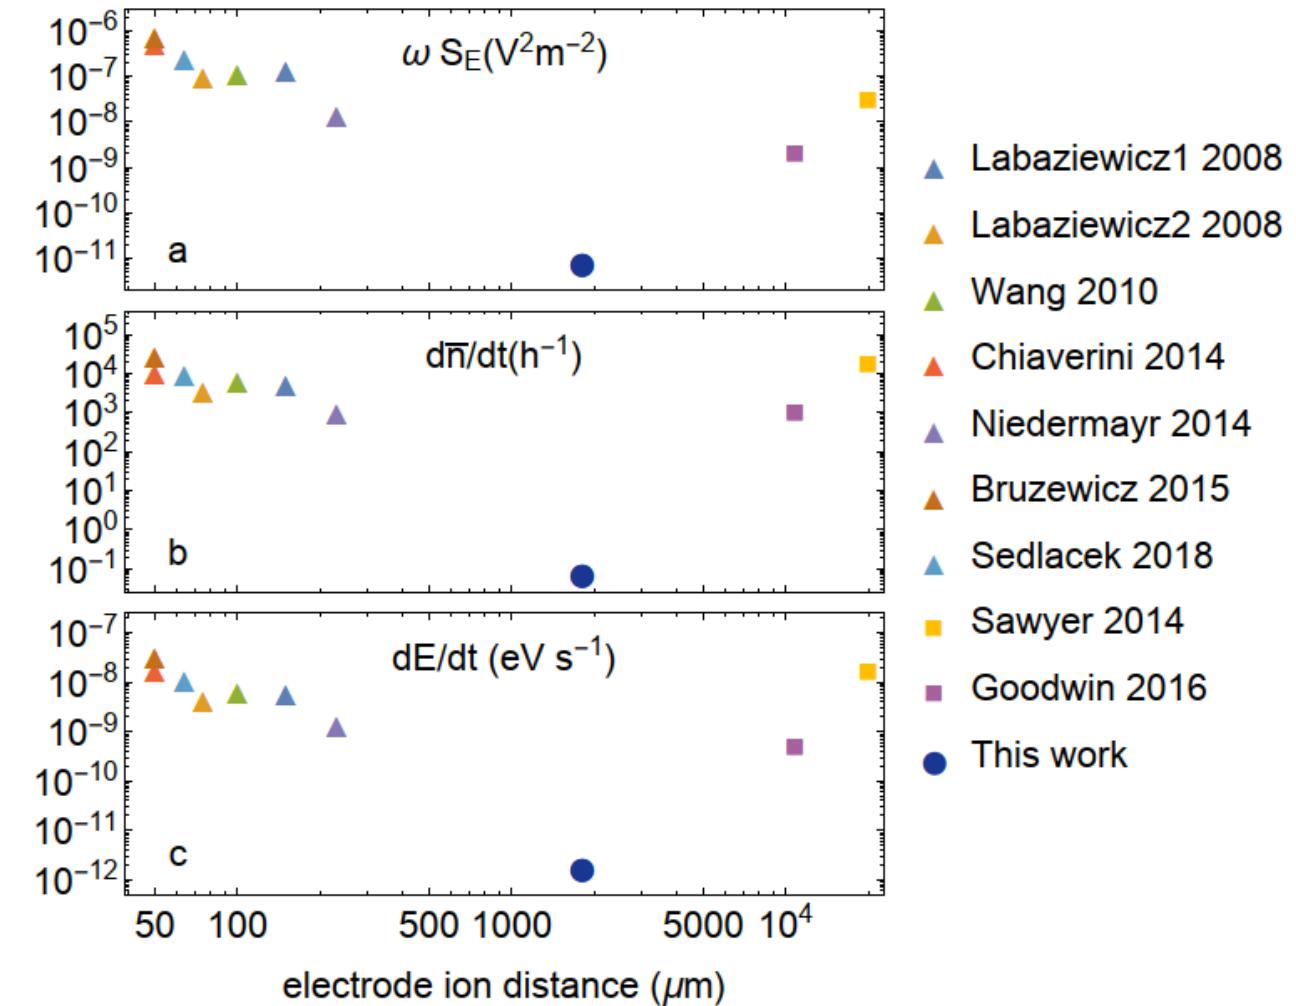

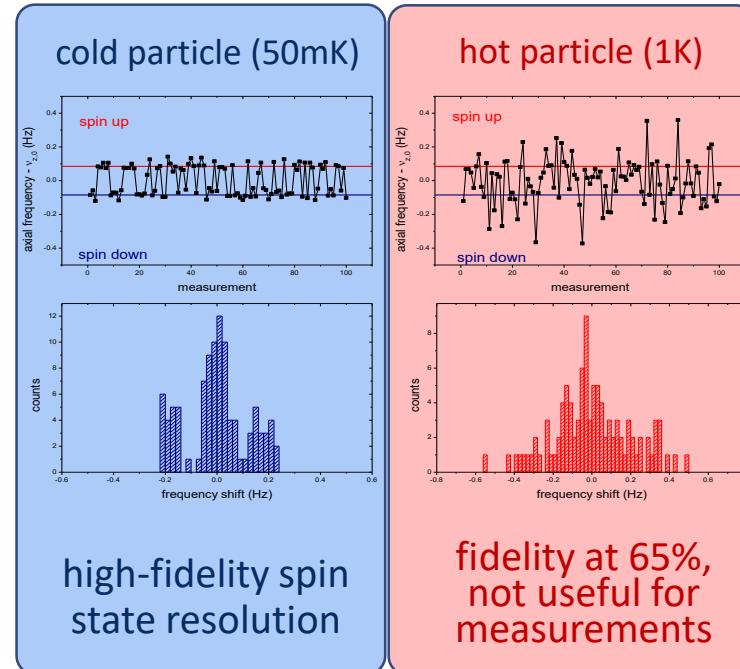

C. Smorra *et al.*, Phys. Lett. B 769, 1 (2017)

- First non-destructive observation of single antiproton spin quantum transitions.

Heating Rates

- Achieve single spin flip resolution only with cold particles.
- Reason: Heating rates scale with particle energy

$$\frac{dn_{+,-}}{dt} \approx \frac{q^2}{2m_p \hbar v_{+,-}} n_{+,-} \Lambda^2 \langle e_n(t), e_n(t-\tau) \rangle$$

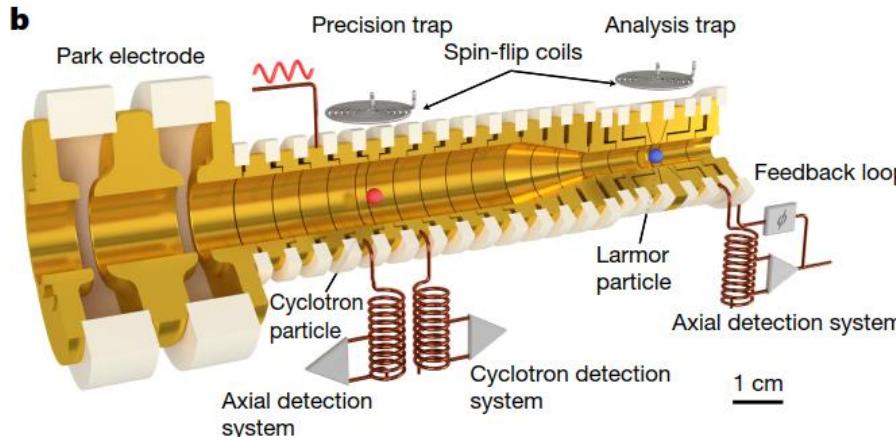

takes hours per preparation cycle

M. J. Borchert, Phys. Rev. Lett. **122**, 043001 (2019)

Invented: BASE Two-Particle Method

Idea: divide measurement to two particles

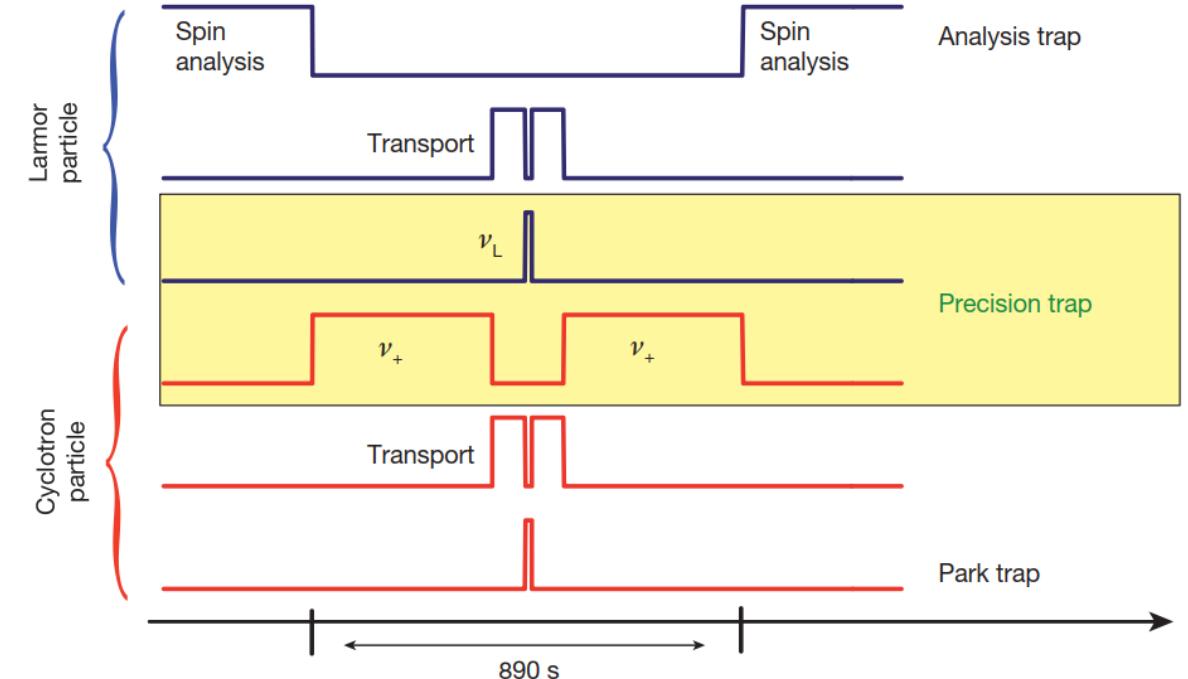

«hot» cyclotron particle which probes the magnetic field in the precision trap

«cold» cyclotron particle to flip and analyze the spin-eigenstate

pay: measure with two particles at different mode energies

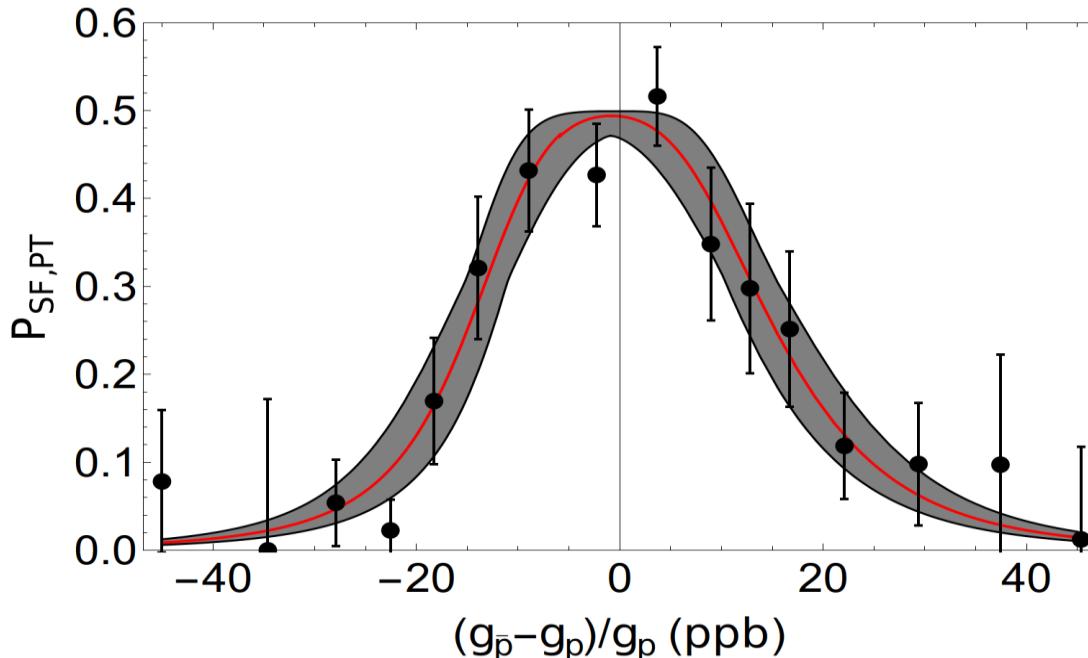

win: 60% of time usually used for sub-thermal cooling useable for measurements

challenges:

- transport without heating
- more challenging systematics

The Magnetic Moment of the Antiproton

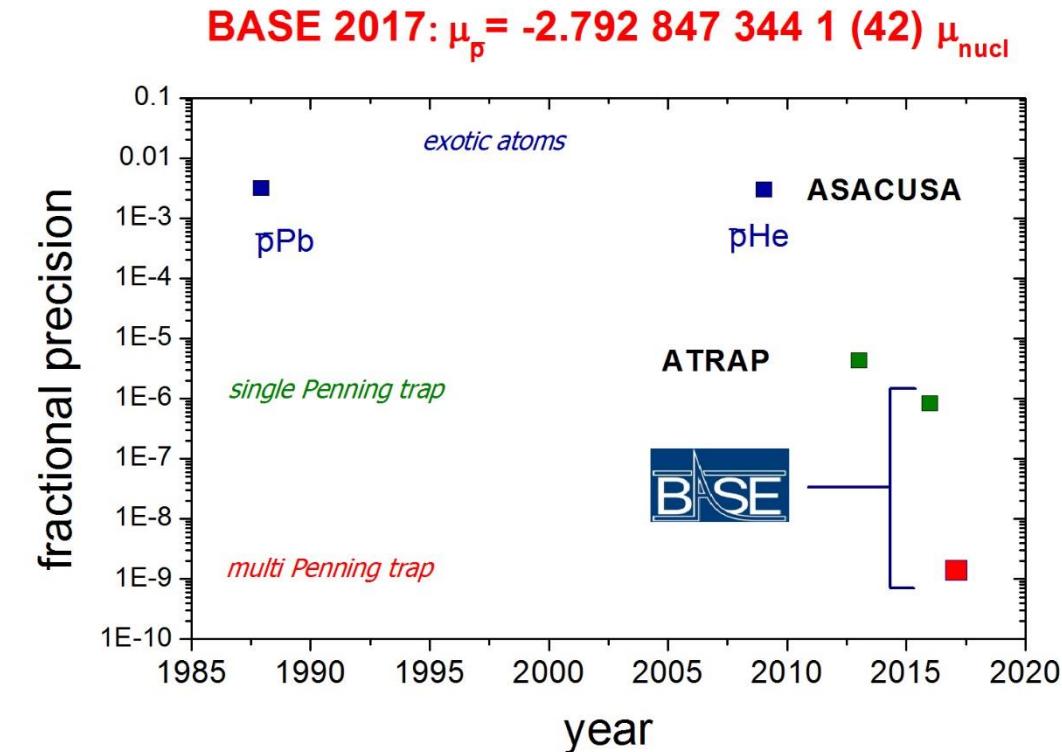

A. Mooser *et al.*, Nature **509**, 596 (2014)

$$\frac{g_p}{2} = 2.792\,847\,350\,(9)$$

$$\frac{g_{\bar{p}}}{2} = 2.792\,847\,344\,1\,(42)$$

C. Smorra *et al.*, Nature **550**, 371 (2017)

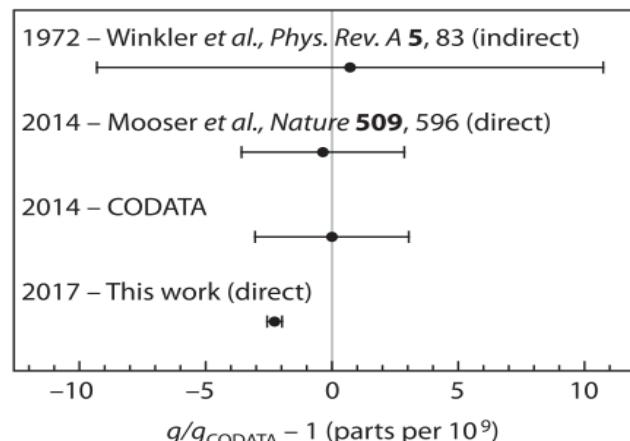

first measurement ever which was more precise for antimatter than for matter conjugate...

...so how about the proton magnetic moment?

The Magnetic Moment of the Proton

Double-trap measurement of the proton magnetic moment at 0.3 parts per billion precision

Georg Schneider,^{1,2*} Andreas Mooser,² Matthew Bohman,^{2,3} Natalie Schön,¹ James Harrington,³ Takashi Higuchi,^{2,4} Hiroki Nagahama,² Stefan Sellner,² Christian Smorra,² Klaus Blaum,³ Yasuyuki Matsuda,⁴ Wolfgang Quint,⁵ Jochen Walz,^{1,6} Stefan Ulmer²

$$\frac{g_p}{2} = 2.792\ 847\ 344\ 62 (82)$$

G. Schneider *et al.*, Science 358, 1081 (2017)

- Plugging all the methods together (in AD)

- New magnetic shielding system
- Phase methods
- Local magnet shims
- new type of trap (cooling trap)

Reach 0.8 ppb frequency scatter (AD limited)

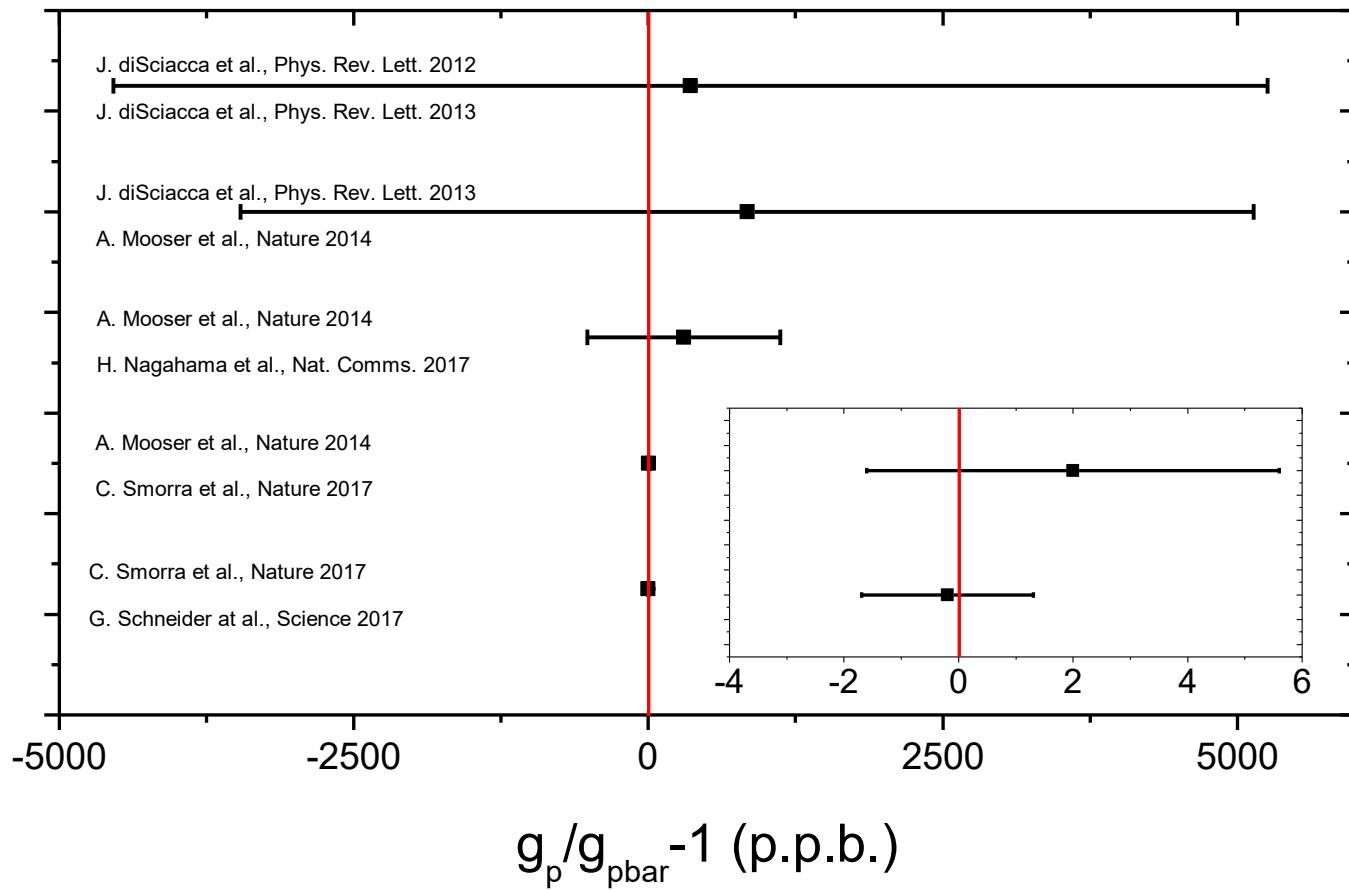

BASE is prepared for antiproton/proton magnetic moment measurements at the level of 100 p.p.t. fractional uncertainty

J. Walz, W. Quint,
Y. Matsuda, C. Ospelkaus

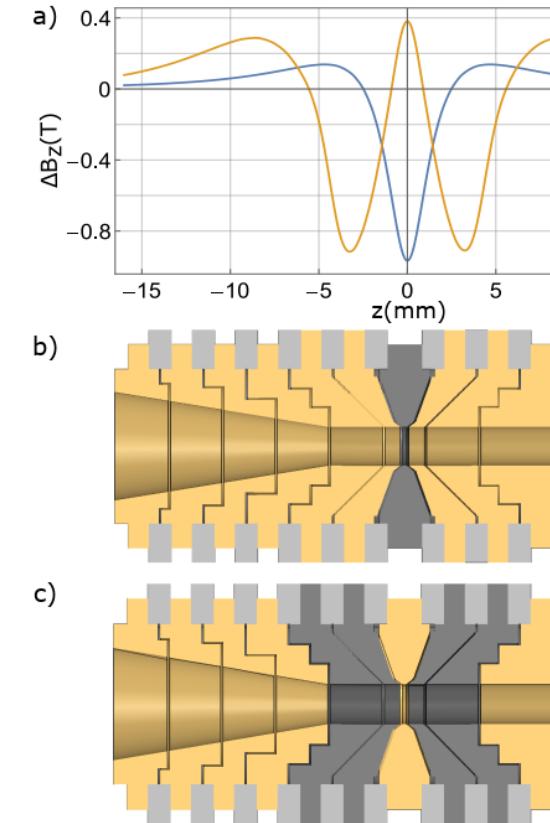

Summary and Outlook

- Performed a 69 p.p.t. - test of CPT invariance with baryons by comparing proton/antiproton charge-to-mass ratios
- Performed the most precise measurement of the proton magnetic moment with a fractional precision of 0.3 p.p.b.
- Performed the most precise measurement of the antiproton magnetic moment with a fractional precision of 1.5 p.p.b.
- Feasibility to improve Q/M comparison by factor of 5 to 10 demonstrated.

Several open positions available in BASE

- Post Doc and PhD positions to
 - Implement transportable antimatter traps
 - Implement sympathetic cooling of antiprotons
 - Develop advanced magnetic shielding systems
 - Implement new Penning trap architectures

...to investigate matter / antimatter asymmetry with highest precision...

SME: $(i\gamma^\mu D_\mu - m) - [a_\mu \gamma^\mu - b_\mu \gamma_5 \gamma^\mu] \psi = 0$

$$b_\mu \gamma_5 \gamma^\mu \rightarrow b_x \begin{pmatrix} -\sigma_x & 0 \\ 0 & \sigma_x \end{pmatrix} + b_y \begin{pmatrix} -\sigma_y & 0 \\ 0 & \sigma_y \end{pmatrix} + b_z \begin{pmatrix} -\sigma_z & 0 \\ 0 & \sigma_z \end{pmatrix}$$

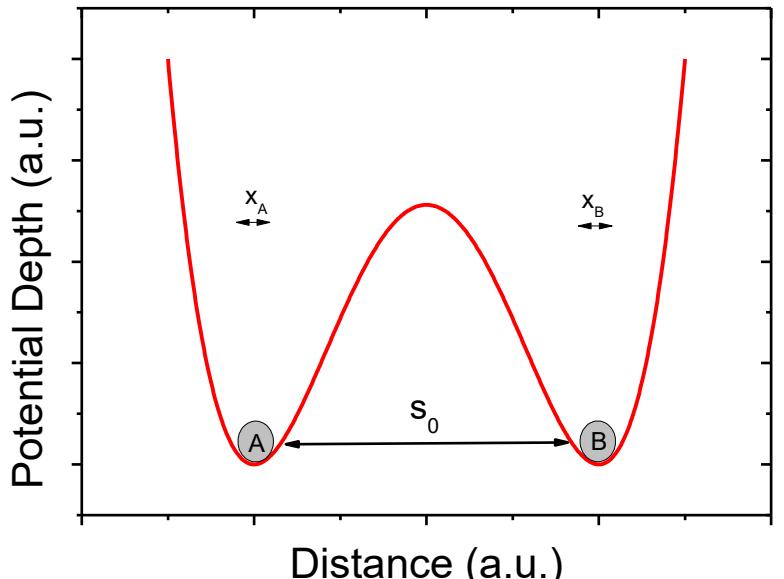

Theoretical framework provided by A. Kostelecky (SME) and Y. Stadnik, V. Flambaum et al.

Sympathetic Cooling of Antiprotons

Goal: Accelerate magnetic moment measurement cycles

Two charged particles trapped in direct vicinity coupled by coulomb interaction.

Of utmost importance for future BASE precision studies

$$U(x_a, x_b) = \frac{1}{4\pi\epsilon_0 s_0} \frac{q_a q_b}{x_a - x_b + s_0}$$

$$\approx \frac{1}{4\pi\epsilon_0 s_0} \frac{q_a q_b}{s_0} \left(1 + \frac{x_a - x_b}{s_0} + \frac{x_a^2}{s_0^2} + \frac{x_b^2}{s_0^2} - \frac{2x_a x_b}{s_0^2} \right)$$

Static

Dynamic

$$-\frac{q_a q_b}{2\pi\epsilon_0 s_0^3} (x'_a x'_b) = -\hbar\Omega_{\text{ex}}(a + a^\dagger)(b + b^\dagger) \approx -\hbar\Omega_{\text{ex}}(ab^\dagger + a^\dagger b) \longrightarrow \Omega_{\text{ex}} \equiv \frac{q_a q_b}{4\pi\epsilon_0 s_0^3 \sqrt{m_a m_b} \sqrt{\omega_{0a} \omega_{0b}}}$$

Resonant Coupling:

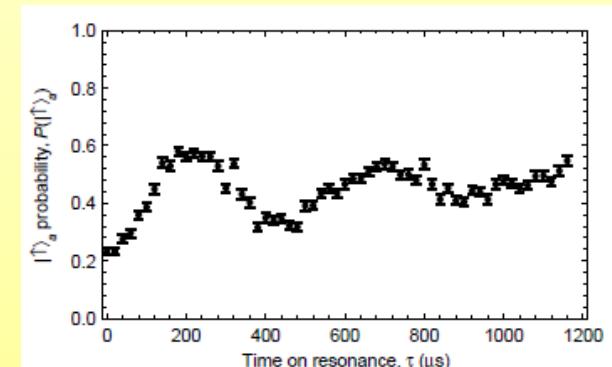

$$a^\dagger(t) = \exp(i\omega_0 t)(a^\dagger(0) \cos(\Omega_{\text{ex}} t) - i b^\dagger(0) \sin(\Omega_{\text{ex}} t))$$

$$b^\dagger(t) = \exp(i\omega_0 t)(b^\dagger(0) \cos(\Omega_{\text{ex}} t) - i a^\dagger(0) \sin(\Omega_{\text{ex}} t))$$

Effective Energy Exchange

Effective Energy Exchange

Successfully demonstrated in Paul trap with Be ions

Publication: K. R. Brown, C. Ospelkaus, Y. Colombe, A. C. Wilson, D. Leibfried, D. J. Wineland, Nature **471**, 196 (2011).

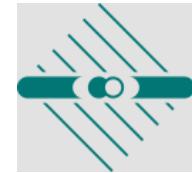

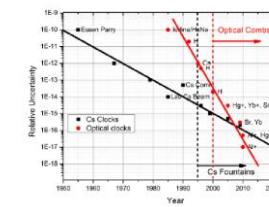

See also: M. Harlander, R. Lechner, M. Brownnutt, R. Blatt, W. Hänsel, Nature **471**, 200 (2011).

Planned Developments – Sympathetic Cooling of pbars

- Current antiproton magnetic moment measurements are limited by particle preparation time and particle mode temperature
- Expect: With traditional methods another 50-fold improvement is possible, **afterwards: limit of traditional methods will be reached!**

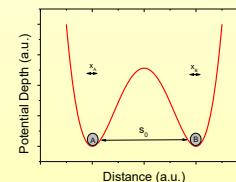

The Vision

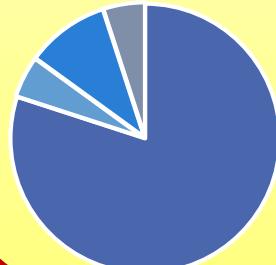

New Method

Couple protons/antiprotons sympathetically to laser cooled ${}^9\text{Be}^+$ ions and imprint Doppler temperatures to the antiproton

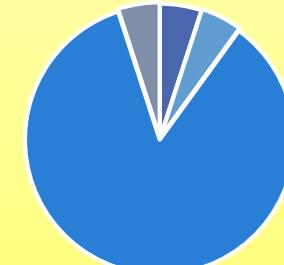

Publication: K. R. Brown, C. Ospelkaus, Y. Colombe, A. C. Wilson, D. Leibfried, D. J. Wineland, *Nature* **471**, 196 (2011).

Current Time Budget

Was demonstrated for ${}^9\text{Be}^+$ ions in Paul traps – implement same in Penning traps

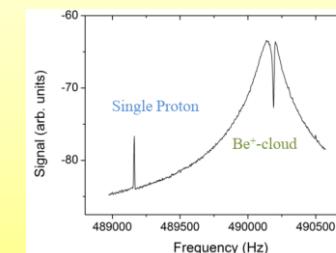

Laser Time Budget

Effort at University of Mainz

5 trap design implemented and simultaneous detection of ${}^9\text{Be}^+$ ion and proton in common endcap trap was demonstrated.

C. Smorra, A. Mooser, M. Bohman, M. Wiesinger et al.

PTB Effort at University of Hannover and PTB

Recent dramatic progress:
Detection of a single laser cooled ${}^9\text{Be}^+$ ion, in a Penning trap system which is fully compatible with the BASE trap system at CERN

J. M. Cornejo, M. Niemann, T. Meiners, J. Mielke, C. Ospelkaus et al.

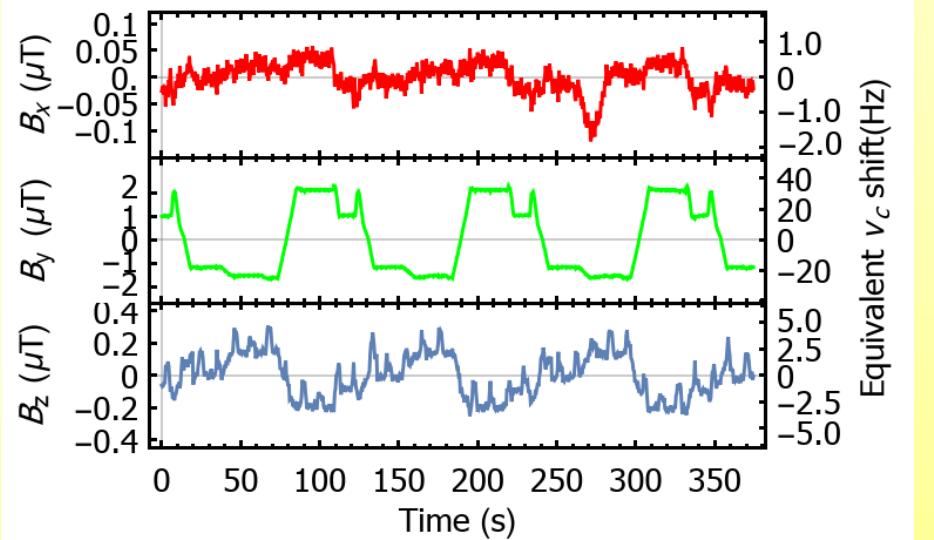

>100-fold improved antiproton cooling time seems to be in reach

Planned Developments – Transportable Antiproton Traps

Why would this make sense?

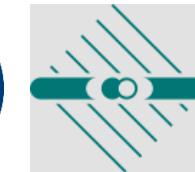

- BASE demonstrated measurements at a level of 20 parts in a trillion $\rightarrow 500\text{uHz}$
- On the other hand:

For measurements at sub-p.p.t. precision particles need to be moved to a dedicated high-precision laboratory.

Feasibility:

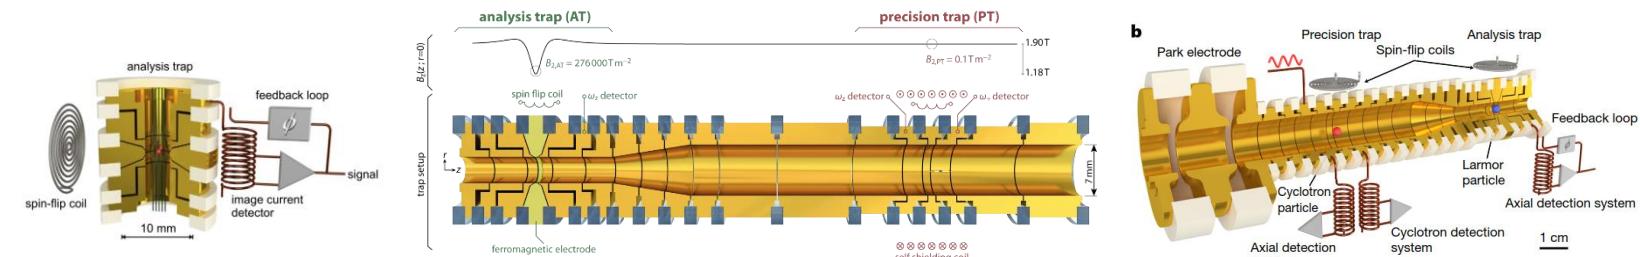

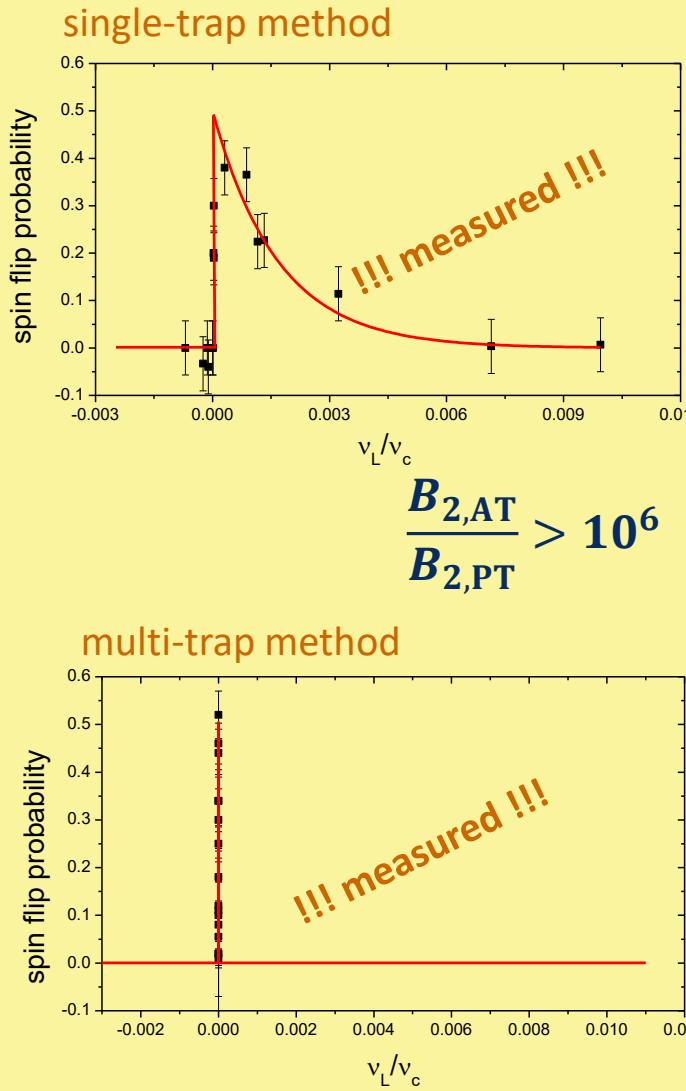

- Need to be able to...:
 - ...catch and cool antiprotons
 - ...store antiprotons for quasi-infinite amount of time
 - ...extract small amount of antiprotons from a large reservoir
 - ...shuttle antiprotons between traps
- Yet to be developed: Transport trap and transfer to another trap experiment

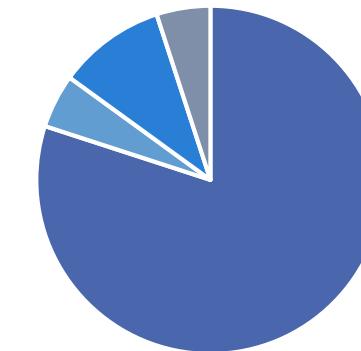

Exciting potential to multiply the antiproton physics program

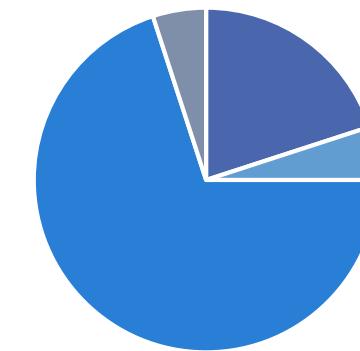

Single Trap – Double Trap – Triple Trap

Time Budget Double Trap

Time Budget Two Particle

■ Cooling ■ Maintenance ■ Measurement ■ Shuttling ■ Cooling ■ Maintenance ■ Measurement ■ Shuttling

two years compared to two months...

Systematics

Table 1 | Error budget of the antiproton magnetic moment measurement

Effect	Correction (p.p.b.)	Uncertainty (p.p.b.)	
Image-charge shift	0.05	0.001	calculate
Relativistic shift	0.03	0.003	measure T / calculate
Magnetic gradient	0.22	0.020	measure / calculate
Magnetic bottle	0.12	0.009	measure / calculate
Trap potential	-0.01	0.001	measure / calculate
Voltage drift	0.04	0.020	measure / calculate
Contaminants	0.00	0.280	measure / constrain
Drive temperature	0.00	0.970	measure / constrain
Spin-state analysis	0.00	0.130	measure / simulate / constrain
Total systematic shift	0.44	1.020	

The table lists the relative systematic shifts (column 2) by which the measured magnetic-moment value was corrected; column 3 is the uncertainty of the correction. Details of these systematic effects and their quantification are given in Methods.

classical trap shifts

shifts induced by 2 particle approach

this dominant error is not present in double trap measurements.
Has been estimated with the conservative 95% C.L.

The Magnetic Moment of the Proton

- Compared to the CERN experiment, the Mainz experiment has:

- more homogeneous magnetic field
- magnetic field has higher stability
- shallower heating rate scaling
- lower detector temperature

accelerator hall

- double-trap measurement at (compare 2014)

A. Mooser *et al.*, Nature **509**, 596 (2014)

- improved magnetic field homogeneity
- improved magnetic field stability (SSC)
- improved cyclotron cooler
- elimination of main systematic limitations

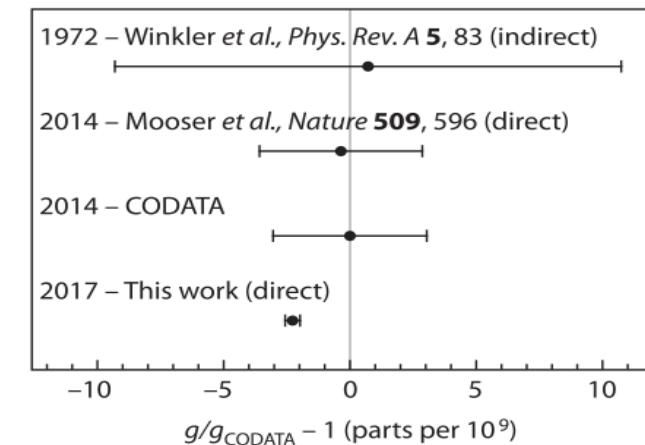

Note: At this level of precision a factor of 11 required 3 years

RESEARCH

NUCLEAR PHYSICS

Double-trap measurement of the proton magnetic moment at 0.3 parts per billion precision

Georg Schneider,^{1,2*} Andreas Mooser,² Matthew Bohman,^{2,3} Natalie Schön,¹ James Harrington,³ Takashi Higuchi,^{2,4} Hiroki Nagahama,² Stefan Sellner,² Christian Smorra,² Klaus Blaum,³ Yasuyuki Matsuda,⁴ Wolfgang Quint,⁵ Jochen Walz,^{1,6} Stefan Ulmer²

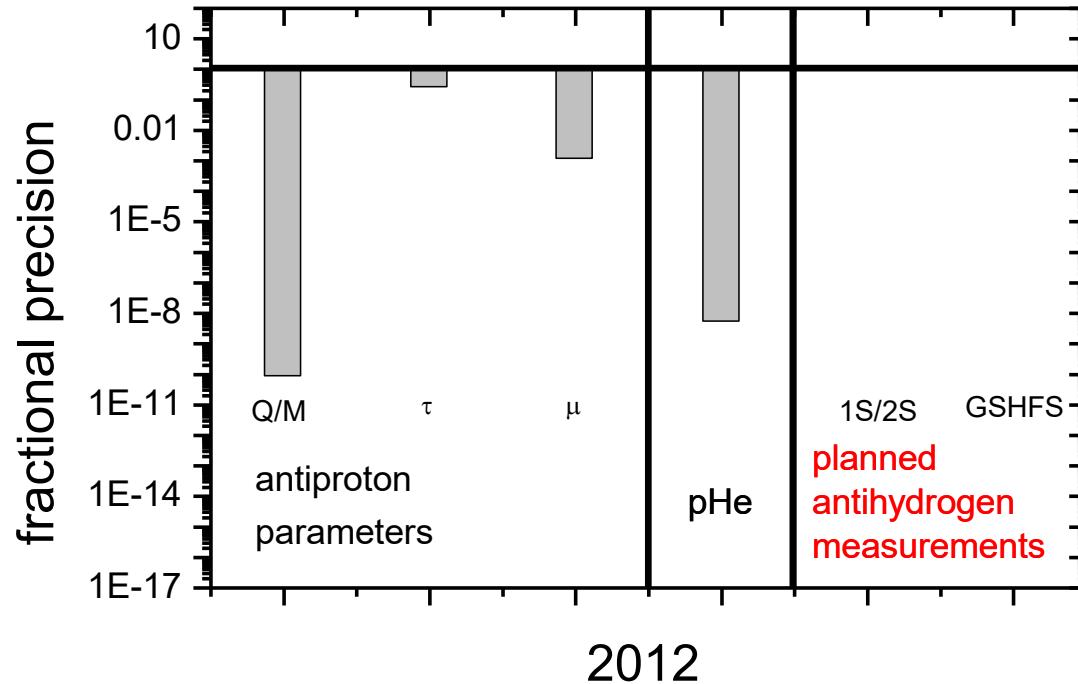

$$\frac{g_p}{2} = 2.792\ 847\ 344\ 62(82)$$

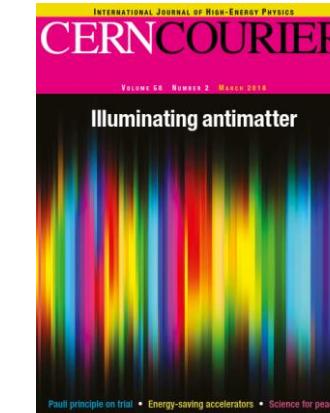

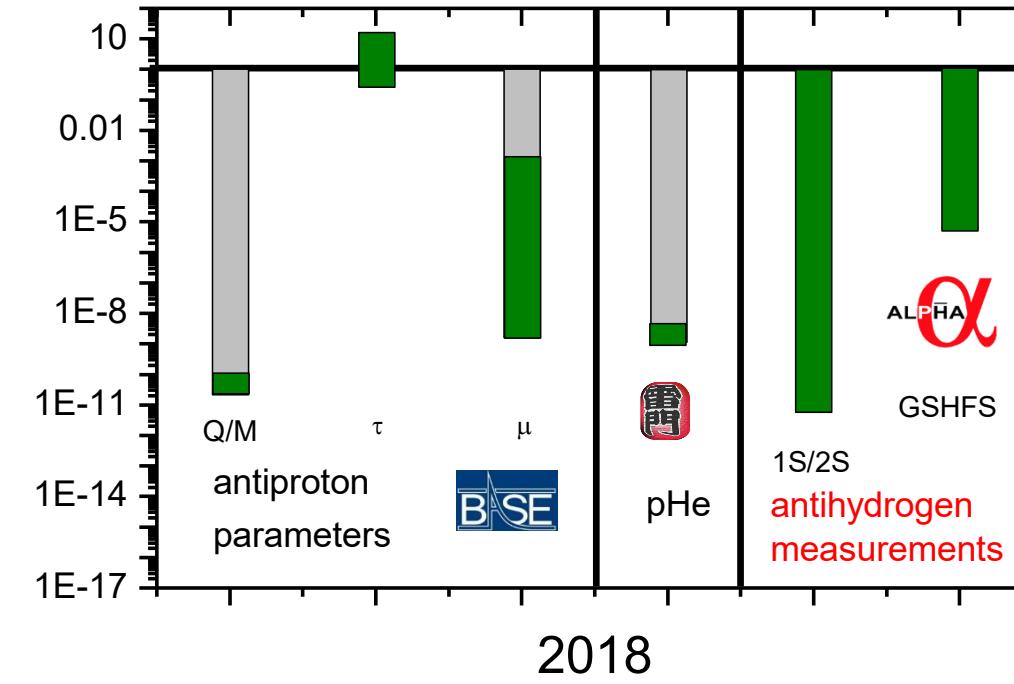

G. Schneider *et al.*, Science **358**, 1081 (2017)

methods developed to improve antiproton moment by at least a factor of 5

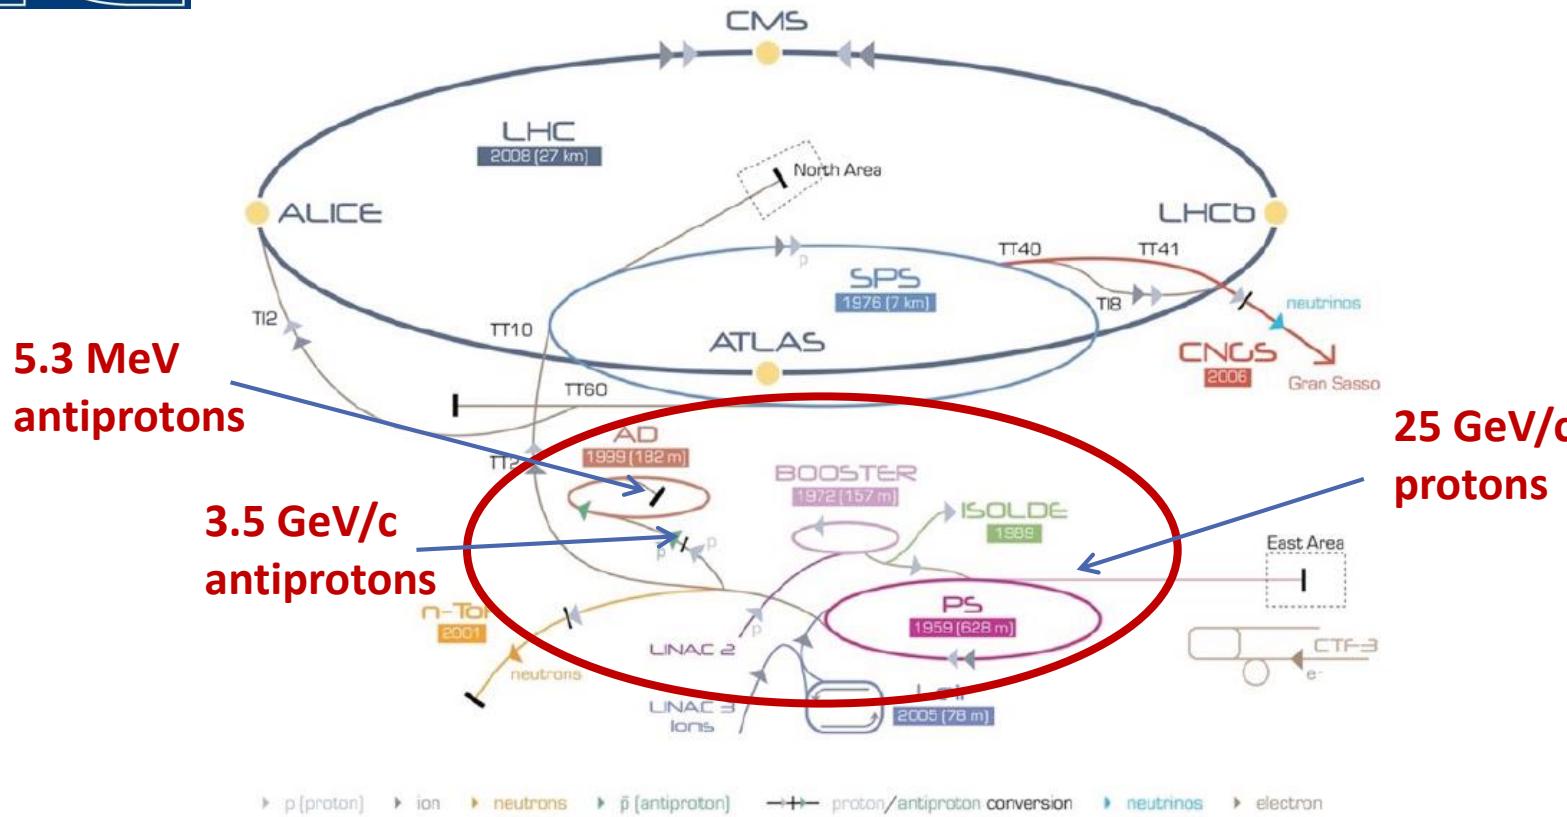

Momentum in the AD community since 2013

- Summarized in CERN courier, issue 2018/03
- J. Hangst – «Illuminating Antimatter»
- S. Ulmer – «Experiment of the Moment»

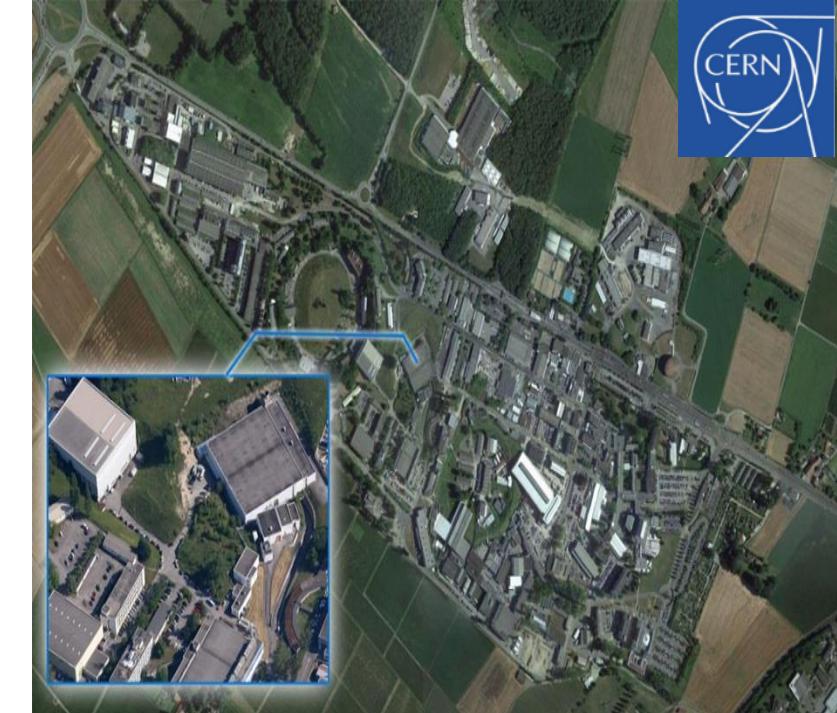

Antiprotons – CERN

- > Degrader -> 1keV
- > Electron cooling -> 0.1 eV
- > Resistive cooling -> 0.000 3 eV
- > Feedback cooling -> 0.000 09 eV

Within a production/deceleration cycle of 120s + 300s of preparation time we bridge **14 orders of magnitude**

Limits on Exotic Physics – ONE example

- Test the Standard Model (CPT invariance) by comparing the fundamental properties of protons and antiprotons with high precision

$$(i\gamma^\mu D_\mu - m) - [a_\mu \gamma^\mu - b_\mu \gamma_5 \gamma^\mu] \psi = 0$$

Dirac equation

CPT-odd modifications

$$b_\mu \gamma_5 \gamma^\mu \rightarrow b_x \begin{pmatrix} -\sigma_x & 0 \\ 0 & \sigma_x \end{pmatrix} + b_y \begin{pmatrix} -\sigma_y & 0 \\ 0 & \sigma_y \end{pmatrix} + b_z \begin{pmatrix} -\sigma_z & 0 \\ 0 & \sigma_z \end{pmatrix}$$

Pseudo-magnetic field, with different coupling to matter and antimatter, respectively

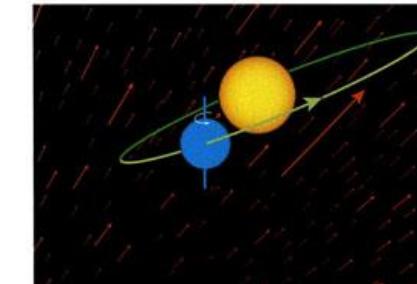

$$\Delta V_{int} = \tilde{b}_{z,D} \begin{pmatrix} 0 & 0 \\ 0 & \pm \sigma_z \end{pmatrix}$$

V. A. Kostelecky, N. Russell,
0801.0287v10 (2017).

Would correspond to the discovery of a boson field which exclusively couples to antimatter.

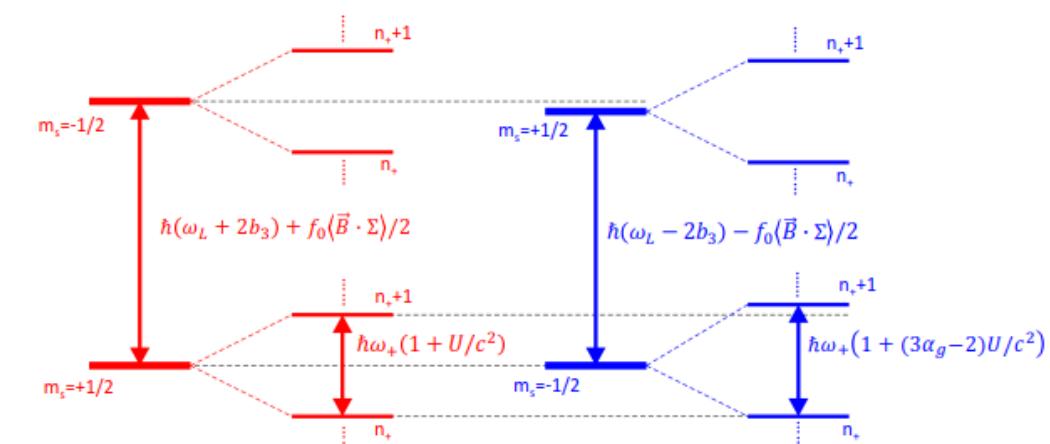

$$H \psi = (H_0 + V_{exotic}) \psi$$

$$\Delta E_{exotic} = \langle \psi | V_{exotic} | \psi \rangle$$

sensitive: comparisons of particle/antiparticle magnetic moments in traps

Frequency Measurements

- Measurement of tiny image currents induced in trap electrodes

- In thermal equilibrium:
 - Particles short noise in parallel
 - Appear as a dip in detector spectrum
 - Width of the dip -> number of particles

$$\Delta\nu = \frac{1}{2\pi} \frac{R}{m} \left(\frac{q}{D} \right)^2 \cdot N$$

- Measurements in thermal equilibrium -> tiny volumina / homogeneous conditions
